Computation: What Is It?

- ♣ **Computation** [The Oxford English Dictionary, 2nd Ed, OUP]
 - ◆ “The action or process of computing, reckoning, or counting; a method or system of reckoning; arithmetical or mathematical calculation.”
- ♣ **Fact (September 2019)**
 - ◆ No word item in the Encyclopædia Britannica, OUP Dictionary of Computer Science, IEEE Standard Computer Dictionary.
 - ◆ What can you think of from this fact?
- ♣ **Fact (at present)**
 - ◆ There is no explicit definition for “computation” that is accepted by all disciplines/scholars.

10/25/22

3

***** Jingde Cheng / Saitama University *****

Computation: What Is It?

- ♣ **The historical origin of “computation”**
 - ◆ The “**decision problem**” (*Entscheidungsproblem*), proposed by Hilbert in 1928, asks for an **effective method** to determine the validity of any given formula in classical predicate calculus.
 - ◆ Effective method: effective procedure, or effectively calculable, means *a FINITE step way (algorithm)*.
- ♣ **Logic is the father/mother of Computer Science**
 - ◆ It is the “decision problem” leads to the notion and/or concept of “computation”, and motivates research on computability.

10/25/22

4

***** Jingde Cheng / Saitama University *****

Computation: What Is It?

- ♣ **The state-of-the-art of computation**
 - ◆ Early equivalent models of computation:
Recursive functions (Herbrand, Gödel, Kleene, 1931-1936),
Lambda calculus (Church, Kleene, 1933-1935),
 - Turing machine** (Turing, 1936-1937),
Post systems (Post, 1936-1943).
 - ◆ Some **Turing-complete** and/or **Turing-equivalent** models of computation: *Combinatory logic*, *Rewriting systems*, *Register machines*, ...
- ♣ **Other models of computation?**
 - ◆ Is there some model of computation that is more “powerful” than Turing-equivalent models?

Turing Machines vs. Finite Automata

• The differences between TMs and FAs

- ◆ A TM can both write on the tape and read from it.
- ◆ The read-write head of a TM can move both to the left and to the right.
- ◆ The tape of a TM is infinite.
- ◆ The special states of a TM for rejecting and accepting take effect immediately.

• The ability of “computation”

- ◆ The TMs are more powerful than FAs.

15

***** Jingde Cheng / Saitama University *****

An Example of Turing Machine: M_1 [S-ToC-13]

• TM M_1

- ◆ Let M_1 be a TM for testing membership in the language $B = \{ w\#w^R \mid w \in \{0, 1\}^* \}$, i.e., we want M_1 to accept if its input is a member of B , two identical strings separated by a # (hash) symbol, and to reject otherwise.
- ◆ Ex: 110101#110101, accept; 110101#101011, reject.

• The working strategy

- ◆ To move back and forth to the corresponding places on the two sides of the # and determine whether they match.
- ◆ To mark places (with some symbol) on the tape to keep track of which places correspond.

10/25/22

14

***** Jingde Cheng / Saitama University *****

An Example of Turing Machine: A Variant of M_1

• TM M'_1

- ◆ Let M'_1 be a TM for testing membership in the language $B = \{ w\#w^R \mid w \in \{0, 1\}^* \}$, i.e., we want M'_1 to accept if its input is a member of B , a string w and its reverse separated by a # (hash) symbol, and to reject otherwise.
- ◆ Ex: 110101#101011, accept; 110101#110101, reject.

• Homework

- ◆ Consider a working strategy of M'_1 .
- ◆ Investigate how many different working strategies might exist.

Turing Machines: Formal Definition [S-ToC-13]

DEFINITION 3.3

A **Turing machine** is a 7-tuple, $(Q, \Sigma, \Gamma, \delta, q_0, q_{\text{accept}}, q_{\text{reject}})$, where Q, Σ, Γ are all finite sets and

1. Q is the set of states,
2. Σ is the input alphabet not containing the **blank symbol** \sqcup ,
3. Γ is the tape alphabet, where $\sqcup \in \Gamma$ and $\Sigma \subseteq \Gamma$,
4. $\delta: Q \times \Gamma \rightarrow Q \times \Gamma \times \{L, R\}$ is the transition function,
5. $q_0 \in Q$ is the start state,
6. $q_{\text{accept}} \in Q$ is the accept state, and
7. $q_{\text{reject}} \in Q$ is the reject state, where $q_{\text{reject}} \neq q_{\text{accept}}$.

10/25/22

18

***** Jingde Cheng / Saitama University *****

• A more accurate/exact definition of transition function

- ◆ $\delta =_{\text{df}} ((Q - \{q_{\text{accept}}, q_{\text{reject}}\}) \times \Gamma) \rightarrow ((Q \times \Gamma) \times \{L, R\})$ (Why?)

Turing Machines: Formal Definition

State set, Input alphabet, and Tape alphabet

- State set Q , Input alphabet Σ , and Tape alphabet Γ all are finite sets.
- $\Sigma \subset \Gamma$, $\square \notin \Sigma$, $\square \in \Gamma$.

Transition function

- Transition function $\delta = (Q \times \Gamma) \rightarrow ((Q \times \Gamma) \times \{L, R\})$ is a function from the Cartesian (direct) product of Q and Γ to the Cartesian (direct) product of $(Q \times \Gamma)$ and $\{L, R\}$.
- $(q_i, a_j) \rightarrow (q_{i+1}, a_{j+1}, L/R)$ means that for a state q_i and the current symbol a_j , the next state and symbol will be q_{i+1} and a_{j+1} , and the next position will be one cell left (L) or right (R) of the current position.
- It is the transition function δ that represents the computation process.

Turing Machines: Languages of Turing Machines

Definition: Language of Turing machine

- [D] The set of strings that M accepts is called the language of M , or the language recognized by M , denoted $L(M)$.
- $L(M) =_{df} \{\omega \mid \omega \in \Sigma^* \text{ and } M \text{ accepts } \omega\}$

Notes

- The language of a TM is an intrinsic property of that TM.
- $L(M)$ may be an infinite (countable) set.

10/25/22

22

***** Jingde Cheng / Saitama University *****

Turing Machines: Formal Definition [L-ToC-17]

DEFINITION 9.1

A Turing machine M is defined by

$$M = (Q, \Sigma, \Gamma, \delta, q_0, \square, F),$$

where

- Q is the set of internal states,
- Σ is the input alphabet,
- Γ is a finite set of symbols called the tape alphabet,
- δ is the transition function,
- $\square \in \Gamma$ is a special symbol called the blank,
- $q_0 \in Q$ is the initial state,
- $F \subseteq Q$ is the set of final states.

In the definition of a Turing machine, we assume that $\Sigma \subseteq \Gamma - \{\square\}$, that is, that the input alphabet is a subset of the tape alphabet, not including the blank. Blanks are ruled out as input for reasons that will become apparent shortly. The transition function δ is defined as

$$\delta : Q \times \Gamma \rightarrow Q \times \Gamma \times \{L, R\}.$$

Languages of Turing Machines [L-ToC-17]

❖ Language of Turing machine

DEFINITION 9.3

Let $M = (Q, \Sigma, \Gamma, \delta, q_0, \square, F)$ be a Turing machine. Then the language accepted by M is

$$L(M) = \left\{ w \in \Sigma^* : q_0 w \xrightarrow{*} x_1 q_f x_2 \text{ for some } q_f \in F, x_1, x_2 \in \Gamma^* \right\}.$$

The symbol $\xrightarrow{*}$ has the usual meaning of an arbitrary number of moves.

❖ The equivalence between two classes of machines

DEFINITION 10.1

Two automata are equivalent if they accept the same language. Consider two classes of automata C_1 and C_2 . If for every automaton M_1 in C_1 , there is an automaton M_2 in C_2 such that

$$L(M_1) = L(M_2),$$

we say that C_2 is at least as powerful as C_1 . If the converse also holds and for every M_2 in C_2 there is an M_1 in C_1 such that $L(M_1) = L(M_2)$, we say that C_1 and C_2 are equivalent.

10/25/22

25

***** Jingde Cheng / Saitama University *****

Turing Machines: Formal Definition [HS-ToC-11]

Formally, a Turing machine is a system

$$M = \langle Q, \Sigma, \Gamma, \delta, q_0, B, q_{\text{accept}}, q_{\text{reject}} \rangle,$$

where

The next move is determined by a *transition function*

Q is the finite set of states,

$\delta : (Q - \{q_{\text{accept}}, q_{\text{reject}}\}) \times \Gamma \rightarrow Q \times \Gamma \times \{L, R\}$.

$B \in \Gamma$, the *blank*,

Σ is the input alphabet, $\Sigma \subseteq \Gamma - \{B\}$,

δ is the transition function,

$q_0 \in Q$ is the *initial state*,

q_{accept} is the accepting state, and

q_{reject} is the rejecting state.

To avoid confusion, we usually take $Q \cap \Gamma = \emptyset$.

10/25/22

26

***** Jingde Cheng / Saitama University *****

Turing Machines: Formal Definition [HS-ToC-11]

Definition 2.1. Let M be a Turing machine. The language *accepted* by M is

$$L(M) = \{w \in \Sigma^* \mid M \text{ accepts } w\}.$$

Definition 2.3. Two Turing machines are *equivalent* if they accept the same language.

10/25/22

27

***** Jingde Cheng / Saitama University *****

Turing Machines: Computation [S-ToC-13]

A Turing machine $M = (Q, \Sigma, \Gamma, \delta, q_0, q_{\text{accept}}, q_{\text{reject}})$ computes as follows. Initially M receives its input $w = w_1 w_2 \dots w_n \in \Sigma^*$ on the leftmost n squares of the tape, and the rest of the tape is blank (i.e., filled with blank symbols). The head starts on the leftmost square of the tape. Note that Σ does not contain the blank symbol, so the first blank appearing on the tape marks the end of the input. Once M has started, the computation proceeds according to the rules described by the transition function. If M ever tries to move its head to the left off the left-hand end of the tape, the head stays in the same place for that move, even though the transition function indicates L. The computation continues until it enters either the accept or reject states at which point it halts. If neither occurs, M goes on forever.

图灵机 $M = (Q, \Sigma, \Gamma, \delta, q_0, q_{\text{accept}}, q_{\text{reject}})$ 的计算方式如下：开始时， M 以最左边的 n 个带方格接收输入 $w = w_1 w_2 \dots w_n \in \Sigma^*$ ，带的其余部分保持空白（即填以空字符），读写头从最左边的带方格开始运行，注意 Σ 不含空字符，故出现在带上的第一个空字符表示输入的结束。 M 开始运行后，计算根据转移函数所描述的规则进行，如果 M 试图将读写头从带的最左端再向左移出，即使转移函数指示的是 L，读写头也停在原地不动。计算一直持续到它进入接受或拒绝状态，此时停机，如果二者都不发生，则 M 将永远运行下去。

28

***** Jingde Cheng / Saitama University *****

Computation of Turing Machines: Formal Definition

❖ Configuration

- ◆ As a TM computes, changes occur in the current state, the current tape contents, and the current head location.
- ◆ A setting of these three items is called *a configuration* of the TM.

❖ Representation of configuration

- ◆ For a state q and two string u and v over the tape alphabet Γ , we write $u q v$ for the configuration where the current state is q , the current tape contents is uv , and the current head location is the first symbol of v .

- ◆ The tape contains only blanks following the last symbol of v .

FIGURE 3.4
A Turing machine with configuration 1011q70111

10/25/22

29

***** Jingde Cheng / Saitama University *****

Computation of Turing Machines: Formal Definition

❖ Configuration transition: regular cases

- ◆ We say that configuration C_1 *yields* configuration C_2 if the TM can legally go from C_1 to C_2 in a single step.

- ◆ For a, b , and c in Γ , u and v in Γ^* , and states

q_i and q_j ,

$ua q_i bv$ yields $u q_j acv$, if $\delta(q_i, b) = (q_j, c, L)$, and

$ua q_i bv$ yields $uac q_j v$, if $\delta(q_i, b) = (q_j, c, R)$.

❖ Note

- ◆ The TM can legally go from C_1 to C_2 in a “SINGLE” step.

10/25/22

30

***** Jingde Cheng / Saitama University *****

Computation of Turing Machines: Formal Definition

• Configuration transition: special case of the left-hand end

- ◆ For the special case of left-hand end,
 $q_i \text{ bv yields } q_j \text{ cv}$, if $\delta(q_i, b) = (q_j, c, L)$
 (because we prevent the machine from going off
 the left-hand end of the tape),
 $q_i \text{ bv yields } c \text{ } q_j \text{ v}$, if $\delta(q_i, b) = (q_j, c, R)$.

• Configuration transition: special case of the right-hand end

- ◆ For the special case of right-hand end,
 $"ua \text{ } q_i"$ is equivalent to $"ua \text{ } q_i \text{ } \square"$
 because we assume that blanks follow the part of the tape
 represented in the configuration. Thus we can handle this
 case as the regular case, with the head no longer at the right-
 hand end.

10/25/22

31

***** Jingde Cheng / Saitama University *****

Computation of Turing Machines: Formal Definition

• Start configuration

- ◆ The start configuration of a TM on input w is the configuration $q_0 w$, which indicates that the machine is in the start state q_0 with its head at the leftmost position on the tape.

• Accepting configuration and Rejecting configuration

- ◆ In an accepting configuration of a TM, the state of the configuration is q_{accept} .
- ◆ In a rejecting configuration of a TM, the state of the configuration is q_{reject} .
- ◆ Accepting configuration and rejecting configuration are halting configurations and do not yield further configurations.

10/25/22

32

***** Jingde Cheng / Saitama University *****

Computation of Turing Machines: Formal Definition [L-ToC-17]

DEFINITION 9.2

Let $M = (Q, \Sigma, \Gamma, \delta, q_0, \square, F)$ be a Turing machine. Then any string $a_1 \cdots a_{k-1} q_1 a_k a_{k+1} \cdots a_n$, with $a_i \in \Gamma$ and $q_i \in Q$, is an instantaneous description of M . A move

$$a_1 \cdots a_{k-1} q_1 a_k a_{k+1} \cdots a_n \vdash a_1 \cdots a_{k-1} b q_2 a_{k+1} \cdots a_n$$

is possible if and only if

$$\delta(q_1, a_k) = (q_2, b, L).$$

A move

$$a_1 \cdots a_{k-1} q_1 a_k a_{k+1} \cdots a_n \vdash a_1 \cdots q_2 a_{k-1} b a_{k+1} \cdots a_n$$

is possible if and only if

$$\delta(q_1, a_k) = (q_2, b, R).$$

M is said to halt starting from some initial configuration $x_1 q_1 x_2$ if

The symbol \vdash has the usual meaning of an arbitrary number of moves.

$$x_1 q_1 x_2 \vdash y_1 q_j y_2$$

for any q_j and a , for which $\delta(q_j, a)$ is undefined. The sequence of configurations leading to a halt state will be called a computation.

10/25/22

33

***** Jingde Cheng / Saitama University *****

Computation of Turing Machines: TMs as Transducers [L-ToC-17]

The input for a computation will be all the nonblank symbols on the tape at the initial time. At the conclusion of the computation, the output will be whatever is then on the tape. Thus, we can view a Turing machine transducer M as an implementation of a function f defined by

$$\hat{w} = f(w),$$

provided that

$$q_0 w \xrightarrow{*} M q_f \hat{w},$$

for some final state q_f .

DEFINITION 9.4

A function f with domain D is said to be **Turing-computable** or just **computable** if there exists some Turing machine $M = (Q, \Sigma, \Gamma, \delta, q_0, \square, F)$ such that

$$q_0 w \xrightarrow{*} M q_f f(w), \quad q_f \in F,$$

for all $w \in D$.

10/25/22

34

***** Jingde Cheng / Saitama University *****

An Example of Turing Machine: Formal Description of M_1 [S-ToC-13]

The following is a formal description of $M_1 = (Q, \Sigma, \Gamma, \delta, q_1, q_{\text{accept}}, q_{\text{reject}})$, the Turing machine that we informally described (page 167) for deciding the language $B = \{w\#w \mid w \in \{0,1\}^*\}$.

- $Q = \{q_1, \dots, q_8, q_{\text{accept}}, q_{\text{reject}}\}$,
- $\Sigma = \{0,1,\#\}$, and $\Gamma = \{0,1,\#,x,\square\}$.
- We describe δ with a state diagram (see the following figure).
- The start, accept, and reject states are q_1 , q_{accept} , and q_{reject} , respectively.

10/25/22

35

***** Jingde Cheng / Saitama University *****

An Example of Turing Machine: State Transition of M_1 [S-ToC-13]

- ◆ Homework: Show a state transition table of the state transition diagram of M_1 .

- ◆ Note: To simplify the figure, we do not show the reject state or the transitions going to the reject state. Those transitions occur implicitly whenever a state lacks an outgoing transition for a particular symbol.

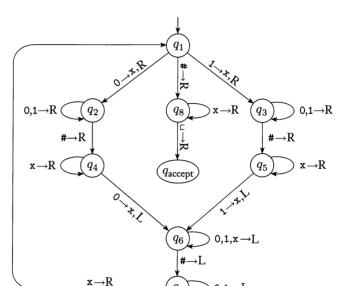

FIGURE 3.10
State diagram for Turing machine M_1

10/25/22

36

***** Jingde Cheng / Saitama University *****

An Example of Turing Machine: State Transition of M_1 [S-ToC-13]

In Figure 3.10, which depicts the state diagram of TM M_1 , you will find the label $0,1 \rightarrow R$ on the transition going from q_3 to itself. That label means that the machine stays in q_3 and moves to the right when it reads a 0 or a 1 in state q_3 . It doesn't change the symbol on the tape.

Stage 1 is implemented by states q_1 through q_6 , and stage 2 by the remaining states. To simplify the figure, we don't show the reject state or the transitions going to the reject state. Those transitions occur implicitly whenever a state lacks an outgoing transition for a particular symbol. Thus, because in state q_5 no outgoing arrow with a # is present, if a # occurs under the head when the machine is in state q_5 , it goes to state q_{reject} . For completeness, we say that the head moves right in each of these transitions to the reject state.

An Example of Turing Machine: M_2 [S-ToC-13]

Now we give the formal description of $M_2 = (Q, \Sigma, \Gamma, \delta, q_1, q_{\text{accept}}, q_{\text{reject}})$:

- $Q = \{q_1, q_2, q_3, q_4, q_5, q_{\text{accept}}, q_{\text{reject}}\}$,
- $\Sigma = \{0\}$, and
- $\Gamma = \{0, x, \sqcup\}$.
- We describe δ with a state diagram (see Figure 3.8).
- The start, accept, and reject states are q_1 , q_{accept} , and q_{reject} .

10/25/22

42

***** Jingde Cheng / Saitama University *****

An Example of Turing Machine: M_2 [S-ToC-13]

- Homework: Show a state transition table of the state transition diagram of M_2 .
- Note: $(q_1, x) \rightarrow (q_{reject}, x, R)$ is a misprint.

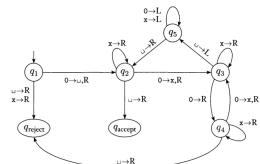

FIGURE 3.8
State diagram for Turing machine M_2

In this state diagram, the label $0 \rightarrow \text{--}, R$ appears on the transition from q_1 to q_2 . This label signifies that, when in state q_1 with the head reading 0, the machine goes to state q_2 , writes -- , and moves the head to the right. In other words, $\delta(q_1, 0) = (q_2, \text{--}, R)$. For clarity we use the shorthand $0 \rightarrow R$ in the transition from q_5 to q_1 , to mean that the machine moves to the right when reading 0 in state q_5 but doesn't alter the tape, so $\delta(q_5, 0) = (q_1, 0, R)$.

An Example of Turing Machine: M_2 [S-ToC-13]

This machine begins by writing a blank symbol over the leftmost 0 on the tape so that it can find the left-hand end of the tape in stage 4. Whereas we would normally use a more suggestive symbol such as # for the left-hand end delimiter, we use a blank here to keep the tape alphabet, and hence the state diagram, small. Example 3.11 gives another method of finding the left-hand end of the tape.

Next we give a sample run of this machine on input 0000. The starting configuration is q_10000 . The sequence of configurations the machine enters appears as follows; read down the columns and left to right.

q_10000	$\sqcup q_5x0x\sqcup$	$\sqcup xq_5xxx\sqcup$
$\sqcup q_2000$	$q_5\sqcup x0x\sqcup$	$\sqcup q_5xxx\sqcup$

An Example of Turing Machine: M_3 [S-ToC-13]

- Show the state transition diagram of the following M_3 .

EXAMPLE 3.11

Here, a TM M_3 is doing some elementary arithmetic. It decides the language $C = \{a^i b^j c^k \mid i \times j = k \text{ and } i, j, k \geq 1\}$.

$M_3 =$ “On input string w :

- Scan the input from left to right to determine whether it is a member of $a^*b^*c^*$ and $reject$ if it isn't.
- Return the head to the left-hand end of the tape.
- Cross off an a and scan to the right until a b occurs. Shuttle between the b 's and the c 's, crossing off one of each until all b 's are gone. If all c 's have been crossed off and some b 's remain, $reject$.
- Restore the crossed off b 's and repeat stage 3 if there is another a to cross off. If all a 's have been crossed off, determine whether all c 's also have been crossed off. If yes, $accept$; otherwise, $reject$.“

An Example of Turing Machine: M_4 [S-ToC-13]

◆ Show the state transition diagram of the following M_4 .

EXAMPLE 3.12

Here, a TM M_4 is solving what is called the *element distances problem*. It is given a list of strings over $\{0,1\}$ separated by $\#$, and its job is to accept if all the strings are different. The language is

$$L = \{\#x_1\#x_2\#\cdots\#x_l \mid \text{each } x_i \in \{0,1\}^* \text{ and } x_i \neq x_j \text{ for each } i \neq j\}.$$

Machine M_4 works by comparing x_1 with x_2 through x_l , then by comparing x_2 with x_3 through x_l , and so on. An informal description of the TM M_4 deciding this language follows.

M_4 = “On input w :

1. Place a mark on top of the leftmost tape symbol. If that symbol is a blank, accept. If that symbol was a $\#$, continue with the next stage. Otherwise, reject.
2. Scan right to the next $\#$ and place a second mark on top of it. If no $\#$ is encountered before a blank symbol, only x_1 was present, so accept.
3. By zig-zagging, compare the two strings to the right of the marked $\#$ s. If they are equal, reject.
4. If no $\#$ symbol is encountered before a blank symbol, move the leftmost mark to the next $\#$ to its right and the rightmost mark to the $\#$ after that. This time, if no $\#$ is available for the rightmost mark, all the strings have been compared, so accept.
5. Go to stage 3.”

Turing Machine Examples [L-ToC-17]

EXAMPLE 9.3

Look at the Turing machine in Figure 9.5. To see what will happen, we can trace a typical case. Suppose that the tape initially contains $ab\dots$, with the read-write head on the a . The machine then reads the a , but does not change it. Its next state is q_1 and the read-write head moves right, so that it is now over the b . This symbol is also read and left unchanged. The machine goes back into state q_0 and the read-write head moves left. We are now back exactly in the original state, and the sequence of moves starts again. It is clear from this that the machine, whatever the initial information on its tape, will run forever, with the read-write head moving alternately right then left, but making no modifications to the tape. This is an instance of a Turing machine that does not halt. In analogy with programming terminology, we say that the Turing machine is in an **infinite loop**.

***** Jingde Cheng / Saitama University *****

Turing Machine Examples [L-ToC-17]

EXAMPLE 9.2

Consider the Turing machine defined by

$$\begin{aligned} Q &= \{q_0, q_1\}, \\ \Sigma &= \{a, b\}, \\ \Gamma &= \{a, b, \square\}, \\ F &= \{q_1\}, \end{aligned}$$

and

$$\begin{aligned} \delta(q_0, a) &= (q_0, b, R), \\ \delta(q_0, b) &= (q_0, b, R), \\ \delta(q_0, \square) &= (q_1, \square, L). \end{aligned}$$

If this Turing machine is started in state q_0 with the symbol a under the read-write head, the applicable transition rule is $\delta(q_0, a) = (q_0, b, R)$. Therefore, the read-write head will replace the a with a b , then move right on the tape. The machine will remain in state q_0 . Any subsequent a will also be replaced with a b , but b 's will not be modified. When the machine encounters the first blank, it will move left one cell, then halt in final state q_1 .

Figure 9.3 shows several stages of the process for a simple initial configuration:

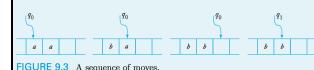

FIGURE 9.3 A sequence of moves.

10/25/22

As before, we can use transition graphs to represent Turing machines. Now we label the edges of the graph with three items: the current tape symbol, the symbol that replaces it, and the direction in which the read-write head is to move. The Turing machine in Example 9.2 is represented by the transition graph in Figure 9.4.

FIGURE 9.4

Turing Machine Examples [L-ToC-17]

EXAMPLE 9.10

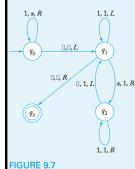

Design a Turing machine that copies strings of 1's. More precisely, find a machine that performs the computation

$$q_0w \xrightarrow{*} q_1ww,$$

for any $w \in \{1\}^+$.

To solve the problem, we implement the following intuitive process:

1. Replace every 1 by a z .
2. Find the rightmost z and replace it with 1.
3. Travel to the right end of the current nonblank region and create a 1 there.
4. Repeat Steps 2 and 3 until there are no more z 's.

The solution is shown in the transition graph in Figure 9.7. It may be a little hard to see at first that the solution is correct, so let us trace the program with the simple string 11. The computation performed in this case is

$$\begin{aligned} q_011 &\vdash xq_01 \vdash xzq_0 \square \vdash xq_1 \\ &\vdash x1q_2 \square \vdash xq_11 \vdash q_1x1 \\ &\vdash 1q_211 \vdash 11q_21 \vdash 111q_2 \square \\ &\vdash 11q_111 \vdash 1q_111 \\ &\vdash q_1111 \vdash q_1 \square 1111 \vdash q_3111. \end{aligned}$$

10/25/22

53

***** Jingde Cheng / Saitama University *****

Turing Machine Examples [L-ToC-17]

EXAMPLE 9.11

Let x and y be two positive integers represented in unary notation. Construct a Turing machine that will halt in a final state q_y if $x \geq y$, and that will halt in a nonfinal state q_x if $x < y$. More specifically, the machine is to perform the computation

$$\begin{cases} q_0w(x)0w(y) \xrightarrow{*} q_0w(x)0w(y) & \text{if } x \geq y, \\ q_0w(x)0w(y) \xrightarrow{*} q_0w(x)0w(y) & \text{if } x < y. \end{cases}$$

To solve this problem, we can use the idea in Example 9.7 with some minor modifications. Instead of matching a's and b's, we match each 1 on the left of the dividing 0 with the 1 on the right. At the end of the matching, we will have on the tape either

$$xx\cdots 11xzx\cdots z\square$$

or

$$xx\cdots xx0zx\cdots z1\square,$$

depending on whether $x > y$ or $y > x$. In the first case, when we attempt to match another 1, we encounter the blank at the right of the working space. This can be used as a signal to enter the state q_y . In the second case, we still find a 1 on the right when all 1's on the left have been replaced, so we use this to get into the final state q_y . The complete program for this computation is left as an exercise.

This example makes the important point that a Turing machine can be programmed to make decisions based on arithmetic comparisons. This kind of simple decision is common in the machine language of computers, where alternate instruction streams are entered, depending on the outcome of an arithmetic operation.

***** Jingde Cheng / Saitama University *****

The Universal Turing Machine

• The transition function δ of M_u

- ♦ With the initial and final state and the blank defined by this convention, any TM can be described completely with transition function δ only.
- ♦ The transition function is encoded according to this scheme, with the arguments and result in some prescribed sequence.
- ♦ For example, $\delta(q_1, a_2) = (q_2, a_3, L)$ might appear as $\cdots 10110110111010 \cdots$.
- ♦ It follows from this that any TM M has a finite encoding as a string on $\{0, 1\}^*$ and that, given any encoding of M , we can decode it uniquely.

10/25/22

63

***** Jingde Cheng / Saitama University *****

The Universal Turing Machine

• The universal (reprogrammable) TM [Turing, 1936]

- ♦ The *universal (reprogrammable) Turing machine M_u* is an automaton that, given as input the description of any TM M and a string w , can simulate the computation of M on w .

• Q and Γ of M_u

- ♦ We assume that $Q = \{q_1, q_2, \dots, q_n\}$, with q_1 the initial state, q_2 the single final state, and $\Gamma = \{a_1, a_2, \dots, a_m\}$, where a_1 represents the blank.
- ♦ We then select an encoding in which q_1 is represented by 1, q_2 is represented by 11, and so on. Similarly, a_1 is encoded as 1, a_2 as 11, etc. The symbol 0 will be used as a separator between the 1's.

10/25/22

62

***** Jingde Cheng / Saitama University *****

The Universal Turing Machine

• Simulating the computation of M on w by M_u

- ♦ For any input M and w , tape 1 will keep an encoded definition of M . Tape 2 will contain the tape contents of M , and tape 3 the internal state of M .
- ♦ M_u looks first at the contents of tapes 2 and 3 to determine the configuration of M .
- ♦ It then consults tape 1 to see what M would do in this configuration.
- ♦ Finally, tapes 2 and 3 will be modified to reflect the result of the move.

65

***** Jingde Cheng / Saitama University *****

The Universal Turing Machine [W-ToC-12]

3.5. A Universal Turing Machine

From the enumeration of all Turing machines and the pairing function we can define a *universal* Turing machine U ; that is, a machine that will emulate *every* other machine. Simply set

$$U(\langle e, x \rangle) = \varphi_e(x).$$

U decodes the single number it receives into a pair (e, x) , decodes e into the appropriate set of quadruples, and uses x as input, acting according to the quadruples it decoded. This procedure is computable because decoding the pairing function, decoding Turing machines from indices, and executing quadruples on a given input are computable procedures. Turing [85] gives an explicit, full construction of a universal machine.

Note that of course there are infinitely many universal Turing machines, as there are for any program via padding, and that a universal machine exists for any collection of functions that may be indexed. Although we will use U and analogously defined universal machines for other indexings in this section, typically we simply refer to the individual indexed functions, using $\varphi_e(x)$ instead of $U(\langle e, x \rangle)$.

10/25/22

66

***** Jingde Cheng / Saitama University *****

The Universal Turing Machine [HS-ToC-11]

Since every word is a number and vice versa, we may think of a Turing-machine code as a number. The code for a Turing machine M is called the *Gödel number* of M . If e is a Gödel number, then M_e is the Turing machine whose Gödel number is e .

Let U be a Turing machine that computes on input e and x and that implements the following algorithm:

```
if  $e$  is a code
  then simulate  $M_e$  on input  $x$ 
  else output 0.
```

(Why are you convinced that a Turing machine with this behavior exists?) U is a *universal* Turing machine. To put it differently, U is a general-purpose, stored-program computer: U accepts as input two values: a “stored program” e , and “input to e ,” a word x . If e is the correct code of a program M_e , then U computes the value of M_e on input x .

Early computers had their programs hard-wired into them. Several years after Turing's 1936 paper, von Neumann and co-workers built the first computer that stored instructions internally in the same manner as data. Von Neumann knew Turing's work, and it is believed that von Neumann was influenced by Turing's universal machine. Turing's machine U is the first conceptual general-purpose, stored-program computer.

10/25/22

67

***** Jingde Cheng / Saitama University *****

The Universal Turing Machine [LP-ToC-98]

Let $M = (K, \Sigma, \delta, s, H)$ be a Turing machine, and let i and j be the smallest integers such that $2^i \geq |K|$, and $2^j \geq |\Sigma| + 2$. Then each state in K will be represented as a q followed by a binary string of length i ; each symbol in Σ will be likewise represented as the letter a followed by a string of j bits. The head directions \leftarrow and \rightarrow will also be treated as “honorary tape symbols” (they were the reason for the “+2” term in the definition of j). We fix the representations of the special symbols $\sqcup, \triangleright, \leftarrow$, and \rightarrow to be the lexicographically four smallest symbols, respectively: \sqcup will always be represented as $a0^j$, \triangleright as $a0^{j-1}1$, \leftarrow as $a0^{j-2}10$, and \rightarrow as $a0^{j-2}11$. The start state will always be represented as the lexicographically first state, $q0^i$. Notice that we require the use of leading zeros in the strings that follow the symbols a and q , to bring the total length to the required level.

We shall denote the representation of the whole Turing machine M as “ M^* . “ M^* consists of the transition table δ . That is, it is a sequence of strings of the form (q, a, p, b) , with q and p representations of states and a, b of symbols, separated by commas and included in parentheses. We adopt the convention that the quadruples are listed in *increasing lexicographic order*, starting with (s, \sqcup) . The set of halting states H will be determined indirectly, by the absence of its states as first components in any quadruple of “ M^* ”. If M decides a language, and thus $H = \{y\}$, we will adopt the convention that y is the lexicographically smallest of the two halt states.

This way, any Turing machine can be represented. We shall use the same method to represent *strings* in the alphabet of the Turing machine. Any string $w \in \Sigma^*$ will have a unique representation, also denoted “ w^* ”, namely, the juxtaposition of the representations of its symbols.

***** Jingde Cheng / Saitama University *****

The Universal Turing Machine [F-ToC-09]

2.4.2 The universal Turing machine

It is possible to give a code for each Turing machine, so that from the code we can retrieve the machine. An easy way of doing this is as follows.

Assume the machine has n states q_0, \dots, q_{n-1} , where each q_i is a number, q_0 is the initial state, and the last m states are final. Also assume that the input alphabet is $\{1\}$ and the tape alphabet is $\{0, 1\}$ (where 0 plays the role of a blank symbol). It is well known that a binary alphabet is sufficient to encode any kind of computation, so there is a loss of generality in this assumption. The transition function can be represented as a table, or equivalently a list of 5-tuples of the form (q, s, q', s', d) , where q represents the current state, s the symbol on the tape under the head, q' the new state, s' the symbol written on the tape, and d the direction of movement, which we will write as 0, 1. The order of the tuples is not important here. Thus, we can assume without loss of generality that the transition function is represented by a list I of tuples. The full description of the machine under these assumptions is given by the tuple (n, m, I) , where I is the list representing the transition function, n the number of states, and m the number of final states, as indicated above. We will say that the tuple is the *code* for the machine since from it we can recover the original machine. In fact, the code for the machine is not unique since we can reorder the list I and still obtain an equivalent machine.

Now we can see the codes of Turing machines as words, and as such they can be used as input for a Turing machine. It is then possible to define a Turing machine U such that, when the code of a machine A is written on the tape, together with an input word w for A , U decodes it and simulates the behaviour of the machine A on w . The machine U is usually called the *universal Turing machine*.

10/25/22

68

***** Jingde Cheng / Saitama University *****

Turing Machines are Countable [L-ToC-17]

THEOREM 10.3

The set of all Turing machines, although infinite, is countable.

Proof: We can encode each Turing machine using 0 and 1. With this encoding, we then construct the following enumeration procedure.

1. Generate the next string in $\{0, 1\}^+$ in proper order.
2. Check the generated string to see if it defines a Turing machine. If so, write it on the tape in the form required by Definition 10.4. If not, ignore the string.
3. Return to Step 1.

Since every Turing machine has a finite description, any specific machine will eventually be generated by this process. ■

A Comparison of Computation Time [J. Cheng]

我们来看一个有关“可计算”问题所需演算步骤的数量化比较。我们考虑A,B,C三个“可计算”问题。假设为了算出最终结果A问题需要n步演算、B问题需要n²(n的2次方)步演算、而C问题需要log2n(以2为底n的对数)步演算，并且还假设这些问题在某种现代通用计算机上被实施计算时每个演算步骤花费的时间为0.001秒，那么关于这三个问题之演算步骤及花费时间的一个数量化对比如下：

	n=2	n=4	n=6	n=30	n=109
B	n ² =4	n ² =16	n ² =36	n ² =900	n ² =1018
C	log2n=1	log2n=2	log2n=3	log2n=5	log2n=30
A	0.002秒	0.004秒	0.006秒	0.030秒	约11天14小时
B	0.004秒	0.016秒	0.036秒	0.9秒	约33,000,000年
C	0.001秒	0.002秒	0.003秒	0.005秒	0.030秒

由上面这个表我们可以看出，以30(36)步和0.03(0.36)秒为基准，三个问题之间的差距是巨大的。

Outcomes of Turing Machine

- ❖ Three possible outcomes of Turing machine
 - ◆ When we start a TM on an input, three outcomes are possible: the TM may accept, reject, or “not halt”.
- ❖ Note
 - ◆ It is often difficult to distinguish a TM that does not halt from one that is merely taking a very long time but will halt at some time.
 - ◆ Therefore, we need a conceptual/theoretical way to distinguish the two cases.

Turing-recognizable (Recursively Enumerable) Languages

♣ Turing-recognizable (recursively enumerable) languages

- ♦ [D] A language is called **Turing-recognizable (recursively enumerable)** if some TM recognizes it, i.e., it may be the language of a TM.

DEFINITION 11.1

A language L is said to be recursively enumerable if there exists a Turing machine that accepts it.

- ♦ [D] A language is called **Turing-unrecognizable** if there is no TM recognizes it.

♣ Notes

- ♦ The “**Turing-recognizability**” of a language is an intrinsic property of that language.
- ♦ For any $w \in \Sigma^*$, if $w \in L(M)$, M must halt and accept w ; but if $w \notin L(M)$, M may halt and reject w or cannot halt.

Language of Turing Machine vs. Turing-recognizable Language

♣ Language of a TM

- ♦ The language of a TM is an intrinsic property of that TM.
- ♦ For a given TM M , we say “ **$L(M)$ is M 's language**”.

♣ Turing-recognizable language

- ♦ The “Turing-recognizability” of a language is an intrinsic property of that language.
- ♦ For a given language L , we consider whether there is a TM that accepts L or not:
if so, then we say “ **L is Turing-recognizable**”,
if not, then we say “ **L is Turing-unrecognizable**”.

10/25/22

81

***** Jingde Cheng / Saitama University *****

Turing Machines as Deciders

♣ Definition: Turing machines as deciders

- ♦ [D] A TM is called **a decider** if it halts on all inputs.
- ♦ [D] A decider that recognizes some language also is said to **decide** that language.

♣ Notes

- ♦ Every decider must be a TM, but some TMs are not deciders.
- ♦ Whether a TM is a decider or not is an intrinsic property of that TM.
- ♦ A decider decides its language.

Turing-decidable (Recursive) Languages

♣ Turing-decidable (recursive) languages

- ♦ [D] A language is called **Turing-decidable (recursive)** or simply **decidable** if some TM M decides it.

DEFINITION 11.2

A language L on Σ is said to be recursive if there exists a Turing machine M that accepts L and that halts on every w in Σ^+ . In other words, a language is recursive if and only if there exists a membership algorithm for it.

♣ Notes

- ♦ The “**Turing-decidability**” of a language is an intrinsic property of that language.
- ♦ For a given language L , we consider whether there is a TM that decides L or not:
if so, then we say “ **L is Turing-decidable**”,
if not, then we say “ **L is Turing-undecidable**”.

The Notion of Algorithm

◆ The notion of algorithm does not exist until the 20th century

- ◆ The notion of “**algorithm**” was not defined precisely until the 20th century.

◆ Hilbert's 10th problem (23 problems in ICM, Paris, 1900)

- ◆ The problem was to devise “a process according to which it can be determined by a **FINITE** number of operations” (i.e., an “**algorithm**”) that tests whether a polynomial Diophantine equation with integer coefficients has an integral root. (**it is undecidable, algorithmically unsolvable**)
- ◆ The solution of the problem had to wait for a clear definition of “**algorithm**”.

◆ The Necessity of the notion of algorithm

- ◆ Proving that an algorithm does not exist requires having a clear definition of algorithm.

10/25/22

94

***** Jingde Cheng / Saitama University *****

Hilbert's 10th Problem as a Decision Problem

◆ Hilbert's 10th problem as a decision problem

- ◆ Let $D = \{p \mid p \text{ is a polynomial Diophantine equation with integer coefficients with an integral root}\}$.
- ◆ The problem asks in essence whether the set D is decidable. (The answer is negative)

◆ D is Turing-recognizable

- ◆ Let $D_1 = \{p \mid p \text{ is a polynomial over } x \text{ with an integral root}\}$
(i.e., p is a polynomial that has only a single variable)
Here is a TM M_1 that recognizes D_1 :

M_1 = “On input $\langle p \rangle$: where p is a polynomial over the variable x .
1. Evaluate p with x set successively to the values $0, 1, -1, 2, -2, 3, -3, \dots$. If at any point the polynomial evaluates to 0, accept.”

If p has an integral root, M_1 eventually will find it and accept. If p does not have an integral root, M_1 will run forever. For the multivariable case, we can present a similar TM M that recognizes D . Here, M goes through all possible settings of its variables to integral values.

The Turing Thesis [L-ToC-17]

♣ The Turing thesis as a definition of mechanical computation

If we take this attitude and regard the Turing thesis simply as a definition, we raise the question as to whether this definition is sufficiently broad. Is it far-reaching enough to cover everything we now do (and conceivably might do in the future) with computers? An unequivocal "yes" is not possible, but the evidence in its favor is very strong. Some arguments for accepting the Turing thesis as the definition of a mechanical computation are

1. Anything that can be done on any existing digital computer can also be done by a Turing machine.
2. No one has yet been able to suggest a problem, solvable by what we intuitively consider an algorithm, for which a Turing machine program cannot be written.
3. Alternative models have been proposed for mechanical computation, but none of them is more powerful than the Turing machine model.

These arguments are circumstantial, and Turing's thesis cannot be proved by them. In spite of its plausibility, Turing's thesis is still an assumption. But viewing Turing's thesis simply as an arbitrary definition misses an important point. In some sense, Turing's thesis plays the same role in computer science as do the basic laws of physics and chemistry.

10/25/22

99

***** Jingde Cheng / Saitama University *****

The Turing Thesis [L-ToC-17]

♣ The Turing thesis as a conjecture/hypothesis

Arguments of this type led A. M. Turing and others in the mid-1930s to the celebrated conjecture called the **Turing thesis**. This hypothesis states that any computation that can be carried out by mechanical means can be performed by some Turing machine.

This is a sweeping statement, so it is important to keep in mind what Turing's thesis is. It is not something that can be proved. To do so, we would have to define precisely the term "mechanical means." This would require some other abstract model and leave us no further ahead than before. The Turing thesis is more properly viewed as a definition of what constitutes a mechanical computation: A computation is mechanical if and only if it can be performed by some Turing machine.

The Church-Turing Thesis [LP-ToC-98]

We therefore propose to adopt the Turing machine that halts on all inputs as the precise formal notion corresponding to the intuitive notion of an "algorithm." Nothing will be considered an algorithm if it cannot be rendered as a Turing machine that is guaranteed to halt on all inputs, and all such machines will be rightfully called algorithms. This principle is known as the **Church-Turing thesis**. It is a thesis, not a theorem, because it is not a mathematical result: It simply asserts that a certain informal concept (algorithm) corresponds to a certain mathematical object (Turing machine). Not being a mathematical statement, the Church-Turing thesis cannot be proved. It is theoretically possible, however, that the Church-Turing thesis could be disproved at some future date, if someone were to propose an alternative model of computation that was publicly acceptable as a plausible and reasonable model of computation, and yet was provably capable of carrying out computations that cannot be carried out by any Turing machine. No one considers this likely.

10/25/22

101

***** Jingde Cheng / Saitama University *****

From Turing Machines to Algorithms

♣ A turning point in the study of the theory of computation

- ◆ We continue to speak of Turing machines, but our real focus from now on is on algorithms.
- ◆ The Turing machine merely serves as a precise model for the definition of algorithm.
- ◆ We skip over the extensive theory of Turing machines themselves and do not spend much time on the low-level programming of Turing machines. We need only to be comfortable enough with Turing machines to believe that they capture all algorithms.

♣ A fundamental problem

- ◆ What is the right level of detail to give when we describe algorithms?

10/25/22

102

***** Jingde Cheng / Saitama University *****

Describing Turing Machine Algorithm: Three Levels of Detail

Formal description (lowest)

- Spelling out in full the TM's states, transition function, and so on; this is the most detailed level of description.

Implementation description

- Using English prose to describe the way that the TM moves its head and the way that it stores data on its tape; at this level we do not give details of states or transition function.

High-level description (highest)

- Using English prose to describe an algorithm, ignoring the implementation details; at this level we do not need mention how the TM manages its tape or head.

10/25/22

103

***** Jingde Cheng / Saitama University *****

Describing Turing Machine Algorithm: Notation and Format

Notation for describing TMs

- The notation for the encoding of an object O into its representation as a string is $\langle O \rangle$.
- If we have several objects O_1, O_2, \dots, O_k , we denote their encoding into a single string $\langle O_1, O_2, \dots, O_k \rangle$.

Format for describing TMs

- We describe TM algorithms with an indented segment of text within quotes.
- We break the algorithm into stages, each usually involving many individual steps of the TM's computation.
- We indicate the block structure of the algorithm with further indentation.

10/25/22

105

***** Jingde Cheng / Saitama University *****

Describing Turing Machine Algorithm: Encoding of Objects

Encoding of objects

- The standard input to a TM is always a string. Therefore, if we want to provide an object other than a string as input, we must first represent that object as a string.

- Strings can represent polynomials, graphs, grammars, automata, and any combination of those objects.

- A TM can be programmed to encode the representations.

Languages as problem representations

- The encoding of an object into its representation is a string.
- Various computational problems can be represented by languages.

10/25/22

104

***** Jingde Cheng / Saitama University *****

Describing Turing Machine Algorithm: An Example [S-ToC-13]

EXAMPLE 3.23

Let A be the language consisting of all strings representing undirected graphs that are connected. Recall that a graph is *connected* if every node can be reached from every other node by traveling along the edges of the graph. We write

$$A = \{\langle G \rangle \mid G \text{ is a connected undirected graph}\}.$$

The following is a high-level description of a TM M that decides A .

M = “On input $\langle G \rangle$, the encoding of a graph G :

- Select the first node of G and mark it.
- Repeat the following stage until no new nodes are marked:
 - For each node in G , mark it if it is attached by an edge to a node that is already marked.
 - Scan all the nodes of G to determine whether they all are marked. If they are, *accept*; otherwise, *reject*.

Describing Turing Machine Algorithm: An Example [S-ToC-13]

10/25/22

109

***** Jingde Cheng / Saitama University *****

Describing Turing Machine Algorithm: An Example [S-ToC-13]

For additional practice, let's examine some implementation-level details of Turing machine M . Usually we won't give this level of detail in the future and you won't need to either, unless specifically requested to do so in an exercise. First, we must understand how $\langle G \rangle$ encodes the graph G as a string. Consider an encoding that is a list of the nodes of G followed by a list of the edges of G . Each node is a decimal number, and each edge is the pair of decimal numbers that represent the nodes at the two endpoints of the edge. The following figure depicts such a graph and its encoding.

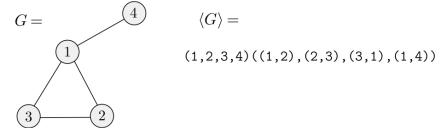

FIGURE 3.24
A graph G and its encoding $\langle G \rangle$

10/25/22

110

***** Jingde Cheng / Saitama University *****

Describing Turing Machine Algorithm: An Example [S-ToC-13]

When M receives the input $\langle G \rangle$, it first checks to determine whether the input is the proper encoding of some graph. To do so, M scans the tape to be sure that there are two lists and that they are in the proper form. The first list should be a list of distinct decimal numbers, and the second should be a list of pairs of decimal numbers. Then M checks several things. First, the node list should contain no repetitions; and second, every node appearing on the edge list should also appear on the node list. For the first, we can use the procedure given in Example 3.12 for TM M_4 that checks element distinctness. A similar method works for the second check. If the input passes these checks, it is the encoding of some graph G . This verification completes the input check, and M goes on to stage 1.

For stage 1, M marks the first node with a dot on the leftmost digit.

For stage 2, M scans the list of nodes to find an undotted node n_1 and flags it by marking it differently—say, by underlining the first symbol. Then M scans the list again to find a dotted node n_2 and underlines it, too.

10/25/22

111

***** Jingde Cheng / Saitama University *****

Describing Turing Machine Algorithm: An Example [S-ToC-13]

Now M scans the list of edges. For each edge, M tests whether the two underlined nodes n_1 and n_2 are the ones appearing in that edge. If they are, M dots n_1 , removes the underlines, and goes on from the beginning of stage 2. If they aren't, M checks the next edge on the list. If there are no more edges, $\{n_1, n_2\}$ is not an edge of G . Then M moves the underline on n_2 to the next dotted node and now calls this node n_2 . It repeats the steps in this paragraph to check, as before, whether the new pair $\{n_1, n_2\}$ is an edge. If there are no more dotted nodes, n_1 is not attached to any dotted nodes. Then M sets the underlines so that n_1 is the next undotted node and n_2 is the first dotted node and repeats the steps in this paragraph. If there are no more undotted nodes, M has not been able to find any new nodes to dot, so it moves on to stage 4.

For stage 4, M scans the list of nodes to determine whether all are dotted. If they are, it enters the accept state; otherwise, it enters the reject state. This completes the description of TM M . ■

Decidable Language Examples: A_{DFA} [S-ToC-13]

• The acceptance problem for DFAs

- ◆ Testing whether a particular DFA accepts a given string can be expressed as a language, A_{DFA} .
- ◆ This language contains the encodings of all DFAs together with strings that the DFAs accept.
- ◆ $A_{DFA} =_{df} \{ \langle B, w \rangle \mid B \text{ is a DFA that accepts input string } w \}$
- ◆ $\langle B, w \rangle \in A_{DFA} = "B \text{ is a DFA that accepts input string } w"$.

• A_{DFA} is decidable

THEOREM 4.1

A_{DFA} is a decidable language.

- ◆ The proof needs to present a TM M that decides A_{DFA} .

10/25/22

113

***** Jingde Cheng / Saitama University *****

Decidable Language Examples: A_{DFA} [S-ToC-13]

• A_{DFA} is decidable: A proof

PROOF IDEA We simply need to present a TM M that decides A_{DFA} .

- $M =$ “On input $\langle B, w \rangle$, where B is a DFA and w is a string:
1. Simulate B on input w .
 2. If the simulation ends in an accept state, *accept*. If it ends in a nonaccepting state, *reject*.”

PROOF We mention just a few implementation details of this proof. For those of you familiar with writing programs in any standard programming language, imagine how you would write a program to carry out the simulation.

First, let's examine the input $\langle B, w \rangle$. It is a representation of a DFA B together with a string w . One reasonable representation of B is simply a list of its five components, Q , Σ , δ , q_0 , and F . When M receives its input, M first determines whether it properly represents a DFA B and a string w . If not, M rejects.

Then M carries out the simulation directly. It keeps track of B 's current state and B 's current position in the input w by writing this information down on its tape. Initially, B 's current state is q_0 and B 's current input position is the leftmost symbol of w . The states and position are updated according to the specified transition function δ . When M finishes processing the last symbol of w , M accepts the input if B is in an accepting state; M rejects the input if B is in a nonaccepting state.

10/25/22

114

***** Jingde Cheng / Saitama University *****

Decidable Language Examples: A_{NFA} [S-ToC-13]

♣ The acceptance problem for NFAs

♦ $A_{\text{NFA}} =_{\text{df}} \{ \langle B, w \rangle \mid B \text{ is a NFA that accepts input string } w \}$

♣ A_{NFA} is decidable

THEOREM 4.2

A_{NFA} is a decidable language.

PROOF We present a TM N that decides A_{NFA} . We could design N to operate like M , simulating an NFA instead of a DFA. Instead, we'll do it differently to illustrate a new idea: Have N use M as a subroutine. Because M is designed to work with DFAs, N first converts the NFA it receives as input to a DFA before passing it to M .

$N =$ “On input $\langle B, w \rangle$, where B is an NFA and w is a string:

1. Convert NFA B to an equivalent DFA C , using the procedure for this conversion given in Theorem 1.39.
2. Run TM M from Theorem 4.1 on input $\langle C, w \rangle$.
3. If M accepts, *accept*; otherwise, *reject*.”

Running TM M in stage 2 means incorporating M into the design of N as a subprocedure.

10/25/22

115

***** Jingde Cheng / Saitama University *****

Decidable Language Examples: E_{DFA} [S-ToC-13]

♣ The emptiness testing problem for DFAs

♦ *Emptiness testing* for the language of a finite automaton: determine whether or not a FA does not accept any strings at all.

♦ $E_{\text{DFA}} =_{\text{df}} \{ \langle A \rangle \mid A \text{ is a DFA and } L(A) = \emptyset \}$

♣ E_{DFA} is decidable

THEOREM 4.4

E_{DFA} is a decidable language.

PROOF A DFA accepts some string iff reaching an accept state from the start state by traveling along the arrows of the DFA is possible. To test this condition, we can design a TM T that uses a marking algorithm similar to that used in Example 3.23.

$T =$ “On input $\langle A \rangle$, where A is a DFA:

1. Mark the start state of A .
2. Repeat until no new states get marked:
3. Mark any state that has a transition coming into it from any state that is already marked.
4. If no accept state is marked, *accept*; otherwise, *reject*.”

Decidable Language Examples: EQ_{DFA} [S-ToC-13]

♣ EQ_{DFA} is decidable

THEOREM 4.5

EQ_{DFA} is a decidable language.

PROOF To prove this theorem, we use Theorem 4.4. We construct a new DFA C from A and B , where C accepts only those strings that are accepted by either A or B but not both. Thus, if A and B recognize the same language, C will accept nothing. The language of C is

$$L(C) = \left(L(A) \cap \overline{L(B)} \right) \cup \left(\overline{L(A)} \cap L(B) \right).$$

This expression is sometimes called the *symmetric difference* of $L(A)$ and $L(B)$ and is illustrated in the following figure. Here, $\overline{L(A)}$ is the complement of $L(A)$. The symmetric difference is useful here because $L(C) = \emptyset$ iff $L(A) = L(B)$. We can construct C from A and B with the constructions for proving the class of regular languages closed under complementation, union, and intersection. These constructions are algorithms that can be carried out by Turing machines. Once we have constructed C , we can use Theorem 4.4 to test whether $L(C)$ is empty. If it is empty, $L(A)$ and $L(B)$ must be equal.

$F =$ “On input $\langle A, B \rangle$, where A and B are DFAs:

1. Construct DFA C as described.
2. Run TM T from Theorem 4.4 on input $\langle C \rangle$.
3. If T accepts, *accept*. If T rejects, *reject*.”

Decidable Language Examples: A_{CFG} [S-ToC-13]

• A_{CFG} is decidable

THEOREM 4.7

A_{CFG} is a decidable language.

PROOF IDEA For CFG G and string w , we want to determine whether G generates w . One idea is to use G to go through all derivations to determine whether any is a derivation of w . This idea doesn't work, as infinitely many derivations may have to be tried. If G does not generate w , this algorithm would never halt. This idea gives a Turing machine that is a recognizer, but not a decider, for A_{CFG} . Turning machine into a decider, we need to ensure that the algorithm tries only finitely many derivations. In Problem 2.26 (page 157) we showed that if G were in Chomsky normal form, any derivation of w has $2n - 1$ steps, where n is the length of w . In that case, checking only derivations with $2n - 1$ steps to determine whether G generates w would be sufficient. Only finitely many such derivations exist. We can convert G to Chomsky normal form by using the procedure given in Section 2.1.

PROOF The TM S for A_{CFG} follows.

$S =$ "On input $\langle G, w \rangle$, where G is a CFG and w is a string:

1. Convert G to an equivalent grammar in Chomsky normal form.
2. List all derivations with $2n - 1$ steps, where n is the length of w ; except if $n = 0$, then instead list all derivations with one step.
3. If any of these derivations generate w , accept; if not, reject."

***** Jingde Cheng / Saitama University *****

Decidable Language Examples: E_{CFG} [S-ToC-13]

• E_{CFG} is decidable

THEOREM 4.8

E_{CFG} is a decidable language.

PROOF IDEA To find an algorithm for this problem, we might attempt to use TM S from Theorem 4.7. It states that we can test whether a CFG generates some particular string w . To determine whether $L(G) = \emptyset$, the algorithm might try going through all possible w 's, one by one. But there are infinitely many w 's to try, so this method could end up running forever. We need to take a different approach.

In order to determine whether the language of a grammar is empty, we need to test whether the start variable can generate a string of terminals. The algorithm does this by solving an emptiness problem. It determines for each variable whether that variable is capable of generating a string of terminals. When the algorithm has determined that a variable can generate some string of terminals, the algorithm keeps track of this information by placing a mark on that variable. The algorithm continues until it finds a variable that cannot generate any strings. It scans all the rules of the grammar. If it ever finds a rule that permits some variable to be replaced by some string of symbols, all of which are already marked, the algorithm knows that this variable can be marked, too. The algorithm continues in this way until it cannot mark any additional variables. The TM R implements this algorithm.

PROOF

$R =$ "On input $\langle G \rangle$, where G is a CFG:

1. Mark all terminal symbols in G .
2. Repeat until no new variables get marked:
 3. Mark any variable A where G has a rule $A \rightarrow U_1U_2 \dots U_k$ and each symbol U_1, \dots, U_k has already been marked.
 4. If the start variable is not marked, accept; otherwise, reject."

Turing-unrecognizable Languages [S-ToC-13]

COROLLARY 4.18

Some languages are not Turing-recognizable.

PROOF To show that the set of all Turing machines is countable, we first observe that the set of all strings Σ^* is countable for any alphabet Σ . With only finitely many strings of each length, we may list a list of Σ^* by writing down all strings of length 0, length 1, length 2, and so on.

The set of all Turing machines is countable because each Turing machine M has an encoding into a string (M). If we simply omit those strings that are not legal encodings of Turing machines, we can obtain a list of all Turing machines.

To show that the set of all languages is uncountable, we first observe that the set of all infinite binary sequences is uncountable. An *infinite binary sequence* is an unending sequence of 0s and 1s. Let B be the set of all infinite binary sequences. We show that B is uncountable by diagonalization similar to the one we used in Theorem 4.17 to show that \mathbb{R} is uncountable.

Let \mathcal{L} be the set of all languages over alphabet Σ . We show that \mathcal{L} is uncountable by giving a correspondence with B , thus showing that the two sets are the same size. Let $\Sigma^* = \{s_1, s_2, s_3, \dots\}$. Each language $A \in \mathcal{L}$ has a unique sequence in B . The i th bit of that sequence is a 1 if $s_i \in A$ and is a 0 if $s_i \notin A$, which is called the *characteristic sequence* of A . For example, if A were the language of all strings starting with a 0 over the alphabet {0,1}, its characteristic sequence x_A would be

$$\begin{aligned} \Sigma^* &= \{ \epsilon, 0, 1, 00, 01, 10, 11, 000, 001, \dots \}; \\ A &= \{ 0, 0, 0, 01, \dots \}; \\ x_A &= \begin{bmatrix} 0 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & \dots \end{bmatrix}. \end{aligned}$$

The function $f: \mathcal{L} \rightarrow B$, where $f(A)$ equals the characteristic sequence of A , is one-to-one and onto, and hence it is a correspondence. Therefore, as B is uncountable, \mathcal{L} is uncountable as well.

130

***** Jingde Cheng / Saitama University *****

The Recognizability of the Language A_{TM}

The A_{TM} is Turing-recognizable

- ♣ A_{TM} is Turing-recognizable
 - ♦ The following TM U (an example of the universal Turing machine) [Turing, 1936] recognizes A_{TM} .
 - ♦ $U = \text{“On input } \langle M, w \rangle, \text{ where } M \text{ is a TM and } w \text{ is a string:}$
 1. Simulate M on input w .
 2. If M ever enters its accept state, accept; if M ever enters its reject state, reject.”
 - ♦ Note U will loop on input $\langle M, w \rangle$ if M loops on w , which is why it does not decide A_{TM} .

10/25/22

132

***** Jingde Cheng / Saitama University *****

Proof of the Undecidability of the Language A_{TM} [S-ToC-13]

PROOF We assume that A_{TM} is decidable and obtain a contradiction. Suppose that H is a decider for A_{TM} . On input $\langle M, w \rangle$, where M is a TM and w is a string, H halts and accepts if M accepts w . Furthermore, H halts and rejects if M fails to accept w . In other words, we assume that H is a TM, where

$$H(\langle M, w \rangle) = \begin{cases} \text{accept} & \text{if } M \text{ accepts } w \\ \text{reject} & \text{if } M \text{ does not accept } w. \end{cases}$$

Now we construct a new Turing machine D with H as a subroutine. This new TM calls H to determine what M does when the input to M is its own description $\langle M \rangle$. Once D has determined this information, it does the opposite. That is, it rejects if M accepts and accepts if M does not accept. The following is a description of D .

$D =$ “On input $\langle M \rangle$, where M is a TM:

1. Run H on input $\langle M, \langle M \rangle \rangle$.
2. Output the opposite of what H outputs. That is, if H accepts, *reject*; and if H rejects, *accept*.”

10/25/22

133

***** Jingde Cheng / Saitama University *****

Proof of the Undecidability of the Language A_{TM} [S-ToC-13]

Don't be confused by the notion of running a machine on its own description! That is similar to running a program with itself as input, something that does occasionally occur in practice. For example, a compiler is a program that translates other programs. A compiler for the language Python may itself be written in Python, so running that program on itself would make sense. In summary,

$$D(\langle M \rangle) = \begin{cases} \text{accept} & \text{if } M \text{ does not accept } \langle M \rangle \\ \text{reject} & \text{if } M \text{ accepts } \langle M \rangle. \end{cases}$$

What happens when we run D with its own description $\langle D \rangle$ as input? In that case, we get

$$D(\langle D \rangle) = \begin{cases} \text{accept} & \text{if } D \text{ does not accept } \langle D \rangle \\ \text{reject} & \text{if } D \text{ accepts } \langle D \rangle. \end{cases}$$

No matter what D does, it is forced to do the opposite, which is obviously a contradiction. Thus, neither TM D nor TM H can exist.

10/25/22

134

***** Jingde Cheng / Saitama University *****

Proof of the Undecidability of the Language A_{TM} [S-ToC-13]

Let's review the steps of this proof. Assume that a TM H decides A_{TM} . Use H to build a TM D that takes an input $\langle M \rangle$, where D accepts its input $\langle M \rangle$ exactly when M does not accept its input $\langle M \rangle$. Finally, run D on itself. Thus, the machines take the following actions, with the last line being the contradiction.

- H accepts $\langle M, w \rangle$ exactly when M accepts w .
- D rejects $\langle M \rangle$ exactly when M accepts $\langle M \rangle$.
- D rejects $\langle D \rangle$ exactly when D accepts $\langle D \rangle$.

10/25/22

135

***** Jingde Cheng / Saitama University *****

Proof of the Undecidability of the Language A_{TM} [S-ToC-13]

Where is the diagonalization in the proof of Theorem 4.11? It becomes apparent when you examine tables of behavior for TMs H and D . In these tables we list all TMs down the rows, M_1, M_2, \dots , and all their descriptions across the columns, $\langle M_1 \rangle, \langle M_2 \rangle, \dots$. The entries tell whether the machine in a given row accepts the input in a given column. The entry is *accept* if the machine accepts the input but is blank if it rejects or loops on that input. We made up the entries in the following figure to illustrate the idea.

	$\langle M_1 \rangle$	$\langle M_2 \rangle$	$\langle M_3 \rangle$	$\langle M_4 \rangle$	\dots
M_1	accept	accept	accept	reject	
M_2	accept	accept	accept	accept	
M_3	reject	reject	reject	reject	
M_4	accept	accept	reject	reject	
\vdots	\vdots	\vdots			

FIGURE 4.19

Entry i, j is *accept* if M_i accepts $\langle M_j \rangle$

10/25/22

136

***** Jingde Cheng / Saitama University *****

Proof of the Undecidability of the Language A_{TM} [S-ToC-13]

In the following figure, the entries are the results of running H on inputs corresponding to Figure 4.19. So if M_3 does not accept input $\langle M_2 \rangle$, the entry for row M_3 and column $\langle M_2 \rangle$ is *reject* because H rejects input $\langle M_3, \langle M_2 \rangle \rangle$.

	$\langle M_1 \rangle$	$\langle M_2 \rangle$	$\langle M_3 \rangle$	$\langle M_4 \rangle$	\dots
M_1	accept	reject	accept	reject	
M_2	accept	accept	accept	accept	
M_3	reject	reject	reject	reject	
M_4	accept	accept	reject	reject	
\vdots	\vdots	\vdots			

FIGURE 4.20

Entry i, j is the value of H on input $\langle M_i, \langle M_j \rangle \rangle$

10/25/22

137

***** Jingde Cheng / Saitama University *****

Proof of the Undecidability of the Language A_{TM} [S-ToC-13]

In the following figure, we added D to Figure 4.20. By our assumption, H is a TM and so is D . Therefore, it must occur on the list M_1, M_2, \dots of all TMs. Note that D computes the opposite of the diagonal entries. The contradiction occurs at the point of the question mark where the entry must be the opposite of itself.

	$\langle M_1 \rangle$	$\langle M_2 \rangle$	$\langle M_3 \rangle$	$\langle M_4 \rangle$	\dots	$\langle D \rangle$	\dots
M_1	accept	reject	accept	reject		accept	
M_2	accept	accept	accept	accept		accept	
M_3	reject	reject	reject	reject		reject	
M_4	accept	accept	reject	reject		accept	
\vdots	\vdots	\vdots					
D	reject	reject	accept	accept		?	
\vdots	\vdots	\vdots

The Undecidability of the Program Termination Problem [HS-ToC-11]

♣ The program termination problem is undecidable

Theorem 3.1. *The Program Termination problem (Example 3.2) is undecidable. There is no algorithm to determine whether an arbitrary partial computable function is total. Thus, there is no algorithm to determine whether a Turing machine halts on every input.*

♣ Notes about proof

- ◆ First, we must encode TMs as words so that TMs can be presented as input strings to other TMs.
- ◆ Second, we construct a universal TM.
- ◆ Third, we represent the problem as a partial computational function.
- ◆ Finally, we use the diagonalization technique to show that no such algorithm exists.

10/25/22

139

***** Jingde Cheng / Saitama University *****

Encoding Turing Machines [HS-ToC-11]

of the details. Suppose we want to encode Turing machine

$$M = \langle Q, \Sigma, \Gamma, \delta, q_0, B, q_{\text{accept}} \rangle.$$

Assume that $Q = \{q_0, q_1, \dots, q_{k-1}\}$. Represent the state q_i by $c(q_i) = [C_2(i)]$, and represent the set of states Q by the string $\{c(q_0), c(q_1), \dots\}$. Similarly, represent Σ and Γ as strings. Write a move $\delta(q_i, a_j) = (q_k, a_l, D)$, where $D = 1$, for a shift left, and $D = 2$, for a shift right, as a five-tuple (q_i, a_j, q_k, a_l, D) . Then, of course, we represent the five-tuple by the string

$$(c(q_i), c(a_j), c(q_k), c(a_l), D).$$

Then δ is a sequence of such five-tuples, so we can represent the sequence as a string as well. Finally, represent the entire seven-tuple that defines M as a string.

10/25/22

140

***** Jingde Cheng / Saitama University *****

Encoding Turing Machines [HS-ToC-11]

Observe that the current representation of a Turing machine M is a word w over the language $\{1, 2, ., ., \{, \}, [,], (,)\}$ consisting of nine symbols. We will make one more refinement. Identify this alphabet with the symbols $\{1, \dots, 9\}$. Then, for each word w over the alphabet $\{1, \dots, 9\}$, let $T(w) = C_2(N_9(w))$. (Recall that $N_9(w)$ is the natural number n whose 9-adic representation is w , and that $C_2(n)$ is the 2-adic representation of n .) $T(w)$ is the result of inputting w to an algorithm that converts 9-adic notation to 2-adic notation, and $T(w)$ is a word over the two-letter alphabet $\{1, 2\}$. For a Turing machine M , where w is the representation of M as a word over the nine-letter alphabet, we call the word $T(w)$ the *encoding* of M .

For each Turing machine M , w_M will denote the word that encodes M . We will say that a problem about Turing machines is *decidable* if the set of words corresponding to Turing machines that satisfy the problem is decidable. Thus, the Program Termination decision problem, stated in Example 3.2, is decidable if and only if $\{w_M \mid M \text{ halts on every input}\}$ is a decidable set. Given M one can effectively find w_M ; conversely, given a word w one can effectively determine whether $w = w_M$ for any M and if so, then effectively find M .

10/25/22

141

***** Jingde Cheng / Saitama University *****

The Universal Turing Machine [HS-ToC-11]

Since every word is a number and vice versa, we may think of a Turing-machine code as a number. The code for a Turing machine M is called the *Gödel number* of M . If e is a Gödel number, then M_e is the Turing machine whose Gödel number is e .

Let U be a Turing machine that computes on input e and x and that implements the following algorithm:

```
if  $e$  is a code
  then simulate  $M_e$  on input  $x$ 
  else output 0.
```

(Why are you convinced that a Turing machine with this behavior exists?) U is a *universal* Turing machine. To put it differently, U is a general-purpose, stored-program computer: U accepts as input two values: a “stored program” e , and “input to e ,” a word x . If e is the correct code of a program M_e , then U computes the value of M_e on input x .

Early computers had their programs hard-wired into them. Several years after Turing’s 1936 paper, von Neumann and co-workers built the first computer that stored instructions internally in the same manner as data. Von Neumann knew Turing’s work, and it is believed that von Neumann was influenced by Turing’s universal machine. Turing’s machine U is the first conceptual general-purpose, stored-program computer.

10/25/22

142

***** Jingde Cheng / Saitama University *****

Representing the problem as a Partial Computational Function [HS-ToC-11]

For every natural number e , define

$$\phi_e = \lambda x. U(e, x)^1$$

If e is a Gödel number, then ϕ_e is the partial function of one argument that is computed by M_e . If e is not the code of any Turing machine, then by the definition of U , $\phi_e(x) = 0$ for all x .

Let’s use the Program Termination problem to illustrate all of this new notation: The Program Termination problem is decidable if and only if

$$\{w_M \mid M \text{ halts on every input}\} = \{e \mid e \text{ is a Gödel number and } \phi_e \text{ halts on every input}\}$$

is decidable, which holds if and only if

$$\{e \mid \phi_e \text{ is total computable}\} = \{e \mid L(M_e) = \Sigma^*\}$$

is decidable. Note that there is an algorithm to determine whether a natural number e is a Gödel number; in case it is not, then, by definition, ϕ_e is total.

Observe that every partial computable function of one argument is ϕ_e for some e , and conversely, every ϕ_e is a partial computable function. Thus, $\{\phi_e\}_{e \geq 0}$ is an *effective enumeration* of the set of all partial computable functions.

10/25/22

143

***** Jingde Cheng / Saitama University *****

Proof of the Undecidability of the Program Termination Problem [HS-ToC-11]

Proof. Suppose there is an algorithm TEST such that, for every i ,

TEST(i) = “yes” if ϕ_i halts on every input value, and
TEST(i) = “no” otherwise.

Define a function δ by

$$\begin{aligned} \delta(k) &= \phi_k(k) + 1 \text{ if TEST}(k) = \text{“yes” and} \\ &\quad \delta(k) = 0 \text{ if TEST}(k) = \text{“no.”} \end{aligned}$$

By definition, δ is defined on every input and δ is computable, so δ is a total computable function. Let e be the Gödel number of a Turing machine that computes δ . Thus, $\delta = \phi_e$ and TEST(e) = “yes.” However, in this case, $\delta(e) = \phi_e(e) + 1$, which contradicts the assertion that $\delta = \phi_e$. Thus, the initial supposition must be false. \square

The Turing-decidability of a Language [S-ToC-13]

THEOREM 4.22

A language is decidable iff it is Turing-recognizable and co-Turing-recognizable.

In other words, a language is decidable exactly when both it and its complement are Turing-recognizable.

PROOF We have two directions to prove. First, if A is decidable, we can easily see that both A and its complement \bar{A} are Turing-recognizable. Any decidable language is Turing-recognizable, and the complement of a decidable language also is decidable.

For the other direction, if both A and \bar{A} are Turing-recognizable, we let M_1 be the recognizer for A and M_2 be the recognizer for \bar{A} . The following Turing machine M is a decider for A .

M = "On input w :

1. Run both M_1 and M_2 on input w in parallel.
2. If M_1 accepts, accept; if M_2 accepts, reject."

Running the two machines in parallel means that M has two tapes, one for simulating M_1 and the other for simulating M_2 . In this case, M takes turns simulating one step of each machine, which continues until one of them accepts.

Now we show that M decides A . Every string w is either in A or \bar{A} . Therefore, either M_1 or M_2 must accept w . Because M halts whenever M_1 or M_2 accepts, M always halts and so it is a decider. Furthermore, it accepts all strings in A and rejects all strings not in A . So M is a decider for A , and thus A is decidable.

Reducibility

◆ Reduction

- ◆ [D] A **reduction** is a way of converting one problem to another problem in such a way that a solution to the second problem can be used to solve the first problem.
- ◆ [D] **Reducibility** always involves two problems, which we call A and B. If problem A reduces to problem B, we can use a solution to B to solve A.
- ◆ Ex: Suppose that you want to find your way around a new city. You know that doing so would be easy if you had a map. Thus, you can reduce the problem of finding your way to the problem of obtaining a map of the city.

◆ Note

- ◆ Reducibility says nothing about solving problem A or problem B alone, but only about the solvability of A in the presence of a solution to B.

10/26/22

154

***** Jingde Cheng / Saitama University *****

Reducibility

◆ The Role of Reducibility

- ◆ Reducibility plays an important role in classifying problems by Turing-decidability in the computability theory, and in the computational complexity theory as well.
- ◆ When A is reducible to B, (algorithmically) solving A cannot be harder than solving B because a (algorithmic) solution to B gives a solution to A.
- ◆ In terms of computability theory, if A is reducible to B and B is decidable, A also is decidable.
- ◆ Equivalently, if A is undecidable and reducible to B, B also is undecidable. This is key to proving that various problems are undecidable.

Proving the Undecidability of the Halting Problem by Reduction [S-ToC-13]

◆ The halting problem

- ◆ $HALT_{TM} = \{ \langle M, w \rangle \mid M \text{ is a TM and } M \text{ halts on input } w \}$

◆ The Undecidability of the halting problem

- ◆ $HALT_{TM}$ is undecidable.

THEOREM 5.1

$HALT_{TM}$ is undecidable.

- ◆ The proof is by contradiction.

- ◆ We assume that $HALT_{TM}$ is decidable and use that assumption to show that A_{TM} is decidable, but this is contradictory to the fact of the undecidability of A_{TM} .

- ◆ The key is to show that A_{TM} is reducible to $HALT_{TM}$.

10/25/22

156

***** Jingde Cheng / Saitama University *****

Proving the Undecidability of the Halting Problem by Reduction [S-ToC-13]

Let's assume that we have a TM R that decides HALT_{TM} . Then we use R to construct S , a TM that decides A_{TM} . To get a feel for the way to construct S , pretend that you are S . Your task is to decide A_{TM} . You are given an input of the form $\langle M, w \rangle$. You must output *accept* if M accepts w , and you must output *reject* if M loops or rejects on w . Try simulating M on w . If it accepts or rejects, do the same. But you may not be able to determine whether M is looping, and in that case your simulation will not terminate. That's bad because you are a decider and thus never permitted to loop. So this idea by itself does not work.

Instead, use the assumption that you have TM R that decides HALT_{TM} . With R , you can test whether M halts on w . If R indicates that M doesn't halt on w , reject because $\langle M, w \rangle$ isn't in A_{TM} . However, if R indicates that M does halt on w , you can do the simulation without any danger of looping.

Thus, if TM R exists, we can decide A_{TM} , but we know that A_{TM} is undecidable. By virtue of this contradiction, we can conclude that R does not exist. Therefore, HALT_{TM} is undecidable.

10/25/22

157

***** Jingde Cheng / Saitama University *****

Proving the Undecidability of the Halting Problem by Reduction [S-ToC-13]

PROOF Let's assume for the purpose of obtaining a contradiction that TM R decides HALT_{TM} . We construct TM S to decide A_{TM} , with S operating as follows.

$S =$ "On input $\langle M, w \rangle$, an encoding of a TM M and a string w :

1. Run TM R on input $\langle M, w \rangle$.
2. If R rejects, *reject*.
3. If R accepts, simulate M on w until it halts.
4. If M has accepted, *accept*; if M has rejected, *reject*."

Clearly, if R decides HALT_{TM} , then S decides A_{TM} . Because A_{TM} is undecidable, HALT_{TM} also must be undecidable.

Theorem 5.1 illustrates our strategy for proving that a problem is undecidable. This strategy is common to most proofs of undecidability, except for the undecidability of A_{TM} itself, which is proved directly via the diagonalization method.

证明 为得到矛盾，假设 TM R 判定 HALT_{TM} ，由之可以构造 TM S 来判定 A_{TM} ，其构造如 F：

$S =$ "在输入 $\langle M, w \rangle$ 上，此处 $\langle M, w \rangle$ 是 TM M 和串 w 的编码：

- 1) 在输入 $\langle M, w \rangle$ 上运行 TM R ，
- 2) 如果 R 拒绝，则拒绝。
- 3) 如果 R 接受，则在 w 上模拟 M ，直到它停机。
- 4) 如果 M 已经接受，则接受；如果 M 已经拒绝，则拒绝。

显然，如果 R 判定 HALT_{TM} ，则 S 判定 A_{TM} 。因为 A_{TM} 是不可判定的，故 HALT_{TM} 也必定是不可判定的。■

定理 5.1 说明了证明问题的不可判定性的方法，此方法对大多数不可判定性证明都适用，只是除了 A_{TM} 本身不可判定性证明之外，它是由对角化方法直接证明的。

The computation history for a TM: Formal Definition [S-ToC-13]

♣ The computation history for a TM

DEFINITION 5.5

Let M be a Turing machine and w an input string. An *accepting computation history* for M on w is a sequence of configurations, C_1, C_2, \dots, C_t , where C_1 is the start configuration of M on w , C_i is an accepting configuration of M , and each C_i legally follows from C_{i-1} according to the rules of M . A *rejecting computation history* for M on w is defined similarly, except that C_i is a rejecting configuration.

♣ Notes

- ♦ Computation histories are finite sequences.
- ♦ If M does not halt on w , no accepting or rejecting computation history exists for M on w .

***** Jingde Cheng / Saitama University *****

Linear Bounded Automata (LBAs) [S-ToC-13]

♣ Linear bounded automata (LBAs)

DEFINITION 5.6

A *linear bounded automaton* is a restricted type of Turing machine wherein the tape head isn't permitted to move off the portion of the tape containing the input. If the machine tries to move its head off either end of the input, the head stays where it is—in the same way that the head will not move off the left-hand end of an ordinary Turing machine's tape.

♣ Notes

- ♦ A *linear bounded automaton (LBA)* is a nondeterministic TM with a limited amount of memory. It can only solve problems requiring memory that can fit within the tape used for the input.

10/26/22

162

***** Jingde Cheng / Saitama University *****

Linear Bounded Automata (LBAs) [L-ToC-17]

DEFINITION 10.5

A linear bounded automaton is a nondeterministic Turing machine $M = (Q, \Sigma, \Gamma, \delta, q_0, \square, F)$, as in Definition 10.2, subject to the restriction that Σ must contain two special symbols $[$ and $]$, such that $\delta(q_i, [)$ can contain only elements of the form $(q_j, [R)$, and $\delta(q_i,])$ can contain only elements of the form $(q_j,], L)$.

DEFINITION 10.6

A string w is accepted by a linear bounded automaton if there is a possible sequence of moves

$$q_0 [w] \xrightarrow{*} [x_1 q_f x_2]$$

for some $q_f \in F, x_1, x_2 \in \Gamma^*$. The language accepted by the lba is the set of all such accepted strings.

Note that in this definition a linear bounded automaton is assumed to be nondeterministic. This is not just a matter of convenience but essential to the discussion of lbas.

10/26/22

163

***** Jingde Cheng / Saitama University *****

Linear Bounded Automata (LBAs) [S-ToC-13]

♣ The power of LBAs

- ♦ Despite their memory constraint, LBAs are quite powerful.
- ♦ The deciders for A_{DFA} , A_{CFG} , E_{DFA} , and E_{CFG} all are LBAs.
- ♦ Every CFL can be decided by an LBA.

♣ A_{LBA} : The acceptance problem of determining whether an LBA accepts its input

- ♦ $A_{\text{LBA}} = \{ \langle M, w \rangle \mid M \text{ is an LBA that accepts input } w \}$
- ♦ Even though A_{LBA} is the same as the undecidable problem A_{TM} where the TM is restricted to be an LBA, we can show that A_{LBA} is decidable.
- ♦ The difference between the decidability of A_{LBA} and the undecidability of A_{TM} shows an intrinsic difference between LBAs and TMs.

The Decidability of A_{LBA} [S-ToC-13]

♣ A limited number of configurations of a LBA

- ♦ An LBA can have only a limited number of configurations when a string of length n is the input.

LEMMA 5.8

Let M be an lba with q states and g symbols in the tape alphabet. There are exactly qnq^n distinct configurations of M for a tape of length n .

♣ A_{LBA} is decidable

- ♦ $A_{\text{LBA}} = \{ \langle M, w \rangle \mid M \text{ is an LBA that accepts input } w \}$
- ♦ A_{LBA} is decidable.

THEOREM 5.9

A_{LBA} is decidable.

10/25/22

165

***** Jingde Cheng / Saitama University *****

Proof of the Decidability of A_{LBA} [S-ToC-13]

PROOF IDEA In order to decide whether lba M accepts input w , we simulate M on w . During the course of the simulation, if M halts and accepts or rejects, we accept or reject accordingly. The difficulty occurs if M loops on w . We need to be able to detect looping so that we can halt and reject.

The idea for detecting when M is looping is that M computes on w , it goes from configuration to configuration. If M ever repeats a configuration, it would go on to repeat this configuration over and over again and thus be in a loop. Because M is an lba, the amount of tape available to it is limited. By Lemma 5.8, M can be in only a limited number of configurations on this amount of tape. Therefore, only a limited amount of time is available to M before it will enter some configuration that it has previously entered. Detecting that M is looping is possible by simulating M for the number of steps given by Lemma 5.8. If M has not halted by then, it must be looping.

PROOF The algorithm that decides A_{LBA} is as follows.

- $L = \{\langle M, w \rangle, \text{ where } M \text{ is an LBA and } w \text{ is a string}\}$
1. Simulate M on w for qnq^n steps or until it halts.
 2. If M has halted, *accept* if it has accepted and *reject* if it has rejected. If it has not halted, *reject*.

If M on w has not halted within qnq^n steps, it must be repeating a configuration according to Lemma 5.8 and therefore looping. That is why our algorithm rejects in this instance.

10/25/22

166

***** Jingde Cheng / Saitama University *****

The Undecidability of E_{LBA} [S-ToC-13]

♣ E_{LBA} is undecidable

- ♦ $E_{\text{LBA}} = \{ \langle M \rangle \mid M \text{ is an LBA and } L(M) = \emptyset \}$
- ♦ E_{LBA} is undecidable.

THEOREM 5.10

E_{LBA} is undecidable.

♣ Proof idea

PROOF IDEA This proof is by reduction from A_{TM} . We show that if E_{LBA} were decidable, A_{TM} would also be. Suppose that E_{LBA} is decidable. How can we use this supposition to decide A_{TM} ?

For a TM M and an input w , we can determine whether M accepts w by constructing a certain lba B and then testing whether $L(B)$ is empty. The language that B recognizes comprises all accepting computation histories for M on w . If M accepts w , this language contains one string and so is nonempty. If M does not accept w , this language is empty. If we can determine whether B 's language is empty, clearly we can determine whether M accepts w .

10/25/22

167

***** Jingde Cheng / Saitama University *****

The Undecidability of E_{LBA} [S-ToC-13]

Now we describe how to construct B from M and w . Note that we need to show more than the mere existence of B . We have to show how a Turing machine can obtain a description of B , given descriptions of M and w .

As in the previous reductions we've given for proving undecidability, we construct B only to feed its description into the presumed E_{LBA} decider, but not to run B on some input.

We construct B to accept its input x if x is an accepting computation history for M on w . Recall that an accepting computation history is the sequence of configurations, C_1, C_2, \dots, C_l that M goes through as it accepts some string w . For the purposes of this proof, we assume that the accepting computation history is presented as a single string with the configurations separated from each other by the $\#$ symbol, as shown in Figure 5.11.

$$\# \underbrace{C_1}_{\text{---}} \# \underbrace{C_2}_{\text{---}} \# \underbrace{C_3}_{\text{---}} \# \cdots \# \underbrace{C_l}_{\text{---}} \#$$

FIGURE 5.11

A possible input to B

10/25/22

168

***** Jingde Cheng / Saitama University *****

The Undecidability of E_{LBA} [S-ToC-13]

The LBA B works as follows. When it receives an input w , B is supposed to accept if w is an accepting computation history for M on w . First, B breaks up w according to the delimiters into strings C_1, C_2, \dots, C_l . Then B determines whether the C_i 's satisfy the three conditions of an accepting computation history.

1. C_1 is the start configuration for M on w .
2. Each C_{i+1} legally follows from C_i .
3. C_l is an accepting configuration for M .

FIGURE 5.11
A possible input to B

The start configuration C_1 for M on w is the string $q_0w_1w_2\dots w_n$, where q_0 is the start state for M on w . Here, B has this string directly built in, so it is able to check the first condition. An accepting configuration is one that contains the q_{accept} state, so B can check the third condition by scanning C_l for q_{accept} . The second condition is the hardest to check. For each pair of adjacent configurations, B checks on whether C_{i+1} legally follows from C_i . This step involves verifying that C_i and C_{i+1} are identical except for the positions under and adjacent to the head in C_i . These positions must be updated according to the transition function of M . Then B verifies that the updating was done properly by zig-zagging between corresponding positions of C_i and C_{i+1} . To keep track of the current positions while zig-zagging, B marks the current position with dots on the tape. Finally, if conditions 1, 2, and 3 are satisfied, B accepts its input.

By inverting the decider's answer, we obtain the answer to whether M accepts w . Thus we can decide A_{TM} , a contradiction.

173

***** Jingde Cheng / Saitama University *****

The Undecidability of E_{LBA} [S-ToC-13]

PROOF Now we are ready to state the reduction of A_{TM} to E_{LBA} . Suppose that TM R decides E_{LBA} . Construct TM S to decide A_{TM} as follows.

$S =$ “On input (M, w) , where M is a TM and w is a string:

1. Construct LBA B from M and w as described in the proof idea.
2. Run R on input $\langle B \rangle$.
3. If R rejects, accept; if R accepts, reject.”

If R accepts $\langle B \rangle$, then $L(B) = \emptyset$. Thus, B has no accepting computation history on w and M doesn't accept w . Consequently, S rejects (M, w) . Similarly, if R rejects $\langle B \rangle$, the language of B is nonempty. The only string that B can accept is an accepting computation history for M on w . Thus, M must accept w . Consequently, S accepts (M, w) . Figure 5.12 illustrates LBA B .

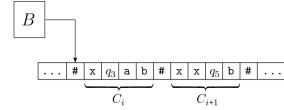

FIGURE 5.12

LBA B checking a TM computation history

10/25/22

170

***** Jingde Cheng / Saitama University *****

The Post Correspondence Problem (PCP) [S-ToC-13]

We can describe this problem easily as a type of puzzle. We begin with a collection of dominos, each containing two strings, one on each side. An individual domino looks like

$$\left[\begin{smallmatrix} a \\ ab \end{smallmatrix} \right]$$

and a collection of dominos looks like

$$\left\{ \left[\begin{smallmatrix} b \\ ca \end{smallmatrix} \right], \left[\begin{smallmatrix} a \\ ab \end{smallmatrix} \right], \left[\begin{smallmatrix} ca \\ a \end{smallmatrix} \right], \left[\begin{smallmatrix} abc \\ c \end{smallmatrix} \right] \right\}$$

The task is to make a list of these dominos (repetitions permitted) so that the string we get by reading off the symbols on the top is the same as the string of symbols on the bottom. This list is called a **match**. For example, the following list is a match for this puzzle.

$$\left[\begin{smallmatrix} a \\ ab \end{smallmatrix} \right] \left[\begin{smallmatrix} b \\ ca \end{smallmatrix} \right] \left[\begin{smallmatrix} ca \\ a \end{smallmatrix} \right] \left[\begin{smallmatrix} a \\ ab \end{smallmatrix} \right] \left[\begin{smallmatrix} abc \\ c \end{smallmatrix} \right].$$

Reading off the top string we get $abcaabc$, which is the same as reading off the bottom. We can also depict this match by deforming the dominos so that the corresponding symbols from top and bottom line up.

10/25/22

172

***** Jingde Cheng / Saitama University *****

The Halting Problem [L-ToC-17]

DEFINITION 12.1

Let w_M be a string that describes a Turing machine $M = (Q, \Sigma, \Gamma, \delta, q_0, \square, F)$, and let w be a string in M 's alphabet. We will assume that w_M and w are encoded as a string of 0's and 1's, as suggested in Section 10.4. A solution of the halting problem is a Turing machine H , which for any w_M and w performs the computation

$$q_0 w_M w \xrightarrow{*} x_1 q_y x_2$$

if M applied to w halts, and

$$q_0 w_M w \xrightarrow{*} y_1 q_n y_2$$

if M applied to w does not halt. Here q_y and q_n are both final states of H .

THEOREM 12.1

There does not exist any Turing machine H that behaves as required by Definition 12.1. The halting problem is therefore undecidable.

10/25/22

174

***** Jingde Cheng / Saitama University *****

Proof of the Undecidability of the Halting Problem [L-ToC-17]

THEOREM 12.1

There does not exist any Turing machine H that behaves as required by Definition 12.1. The halting problem is therefore undecidable.

Proof: We assume the contrary, namely, that there exists an algorithm, and consequently some Turing machine H , that solves the halting problem. The input to H will be the string $w_M w$. The requirement is then that, given any $w_M w$, the Turing machine H will halt with either a yes or no answer. We achieve this by asking that H halt in one of two corresponding final states, say, q_y or q_n . The situation can be visualized by a block diagram like Figure 12.1. The intent of this diagram is to indicate that, if H is started in state q_0 with input $w_M w$, it will eventually halt in state q_y or q_n . As required by Definition 12.1, we want H to operate according to the following rules:

if M applied to w halts, and

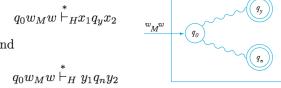

FIGURE 12.1

if M applied to w does not halt.

175

***** Jingde Cheng / Saitama University *****

10/25/22

Proof of the Undecidability of the Halting Problem [L-ToC-17]

Next, we modify H to produce a Turing machine H' with the structure shown in Figure 12.2. With the added states in Figure 12.2 we want to convey that the transitions between state q_0 and the new states q_a and q_b are to be made, regardless of the tape symbol, in such a way that the tape remains unchanged. The way this is done is straightforward. Comparing H and H' we see that, in situations where H reaches q_y and halts, the modified machine H' will enter an infinite loop. Formally, the action of H' is described by

if M applied to w halts, and

$q_0 w_M w \xrightarrow{H'} y_1 q_n y_2$

if M applied to w does not halt.

From H' we construct another Turing machine \tilde{H} . This new machine takes as input w_M and copies it, ending in its initial state q_0 . After that, it behaves exactly like H' . Then the action of \tilde{H} is such that

$q_0 w_M \xrightarrow{\tilde{H}} q_0 w_M w_M \xrightarrow{\tilde{H}} \infty$

if M applied to w_M halts, and

$q_0 w_M \xrightarrow{\tilde{H}} q_0 w_M w_M \xrightarrow{\tilde{H}} y_1 q_n y_2$

if M applied to w_M does not halt.

10/25/22

176

***** Jingde Cheng / Saitama University *****

FIGURE 12.2

Proof of the Undecidability of the Halting Problem [L-ToC-17]

Now \tilde{H} is a Turing machine, so it has a description in $\{0, 1\}^*$, say, \hat{w} . This string, in addition to being the description of \tilde{H} , also can be used as input string. We can therefore legitimately ask what would happen if \tilde{H} is applied to \hat{w} . From the above, identifying M with \tilde{H} , we get

$q_0 \hat{w} \xrightarrow{\tilde{H}} \infty$

if \tilde{H} applied to \hat{w} halts, and

$q_0 \hat{w} \xrightarrow{\tilde{H}} y_1 q_n y_2$

if \tilde{H} applied to \hat{w} does not halt. This is clearly nonsense. The contradiction tells us that our assumption of the existence of H , and hence the assumption of the decidability of the halting problem, must be false. ■

Proof of the Undecidability of the Halting Problem [L-ToC-17]

THEOREM 12.2

If the halting problem were decidable, then every recursively enumerable language would be recursive. Consequently, the halting problem is undecidable.

Proof: To see this, let L be a recursively enumerable language on Σ , and let M be a Turing machine that accepts L . Let H be the Turing machine that solves the halting problem. We construct from this the following procedure:

1. Apply H to $w_M w$. If H says “no,” then by definition w is not in L .
2. If H says “yes,” then apply M to w . But M must halt, so it will eventually tell us whether w is in L or not.

This constitutes a membership algorithm, making L recursive. But we already know that there are recursively enumerable languages that are not recursive. The contradiction implies that H cannot exist, that is, that the halting problem is undecidable. ■

To Reduce the Halting Problem to the State-entry Problem [L-ToC-17]

EXAMPLE 12.1

The **state-entry problem** is as follows. Given any Turing machine $M = (Q, \Sigma, \Gamma, \delta, q_0, \square, F)$ and any $q \in Q$, $w \in \Sigma^+$, decide whether or not the state q is ever entered when M is applied to w . This problem is undecidable.

To reduce the halting problem to the state-entry problem, suppose that we have an algorithm A that solves the state-entry problem. We could then use it to solve the halting problem. For example, given any M and w , we first modify M to get \tilde{M} in such a way that \tilde{M} halts in state q if and only if M halts. We can do this simply by looking at the transition function δ of M . If M halts, it does so because some $\delta(q_i, a)$ is undefined. To get \tilde{M} , we change every such undefined δ to

$$\delta(q_i, a) = (q, a, R),$$

where q is a final state. We apply the state-entry algorithm A to (\tilde{M}, q, w) . If A answers yes, that is, the state q is entered, then (M, w) halts. If A says no, then (M, w) does not halt.

Thus, the assumption that the state-entry problem is decidable gives us an algorithm for the halting problem. Because the halting problem is undecidable, the state-entry problem must also be undecidable.

***** Jingde Cheng / Saitama University *****

To Reduce the Halting Problem to the Blank-tape Halting Problem [L-ToC-17]

EXAMPLE 12.2

The **blank-tape halting problem** is another problem to which the halting problem can be reduced. Given a Turing machine M , determine whether or not M halts if started with a blank tape. This is undecidable.

To show how this reduction is accomplished, assume that we are given some M and some w . We first construct from M a new machine M_w that starts with a blank tape, writes w on it, then positions itself in a configuration $q_0 w$. After that, M_w acts like M . Clearly M_w will halt on a blank tape if and only if M halts on w .

Suppose now that the blank-tape halting problem were decidable. Given any (M, w) , we first construct M_w , then apply the blank-tape halting problem algorithm to it. The conclusion tells us whether M applied to w will halt. Since this can be done for any M and w , an algorithm for the blank-tape halting problem can be converted into an algorithm for the halting problem. Since the latter is known to be undecidable, the same must be true for the blank-tape halting problem.

To Reduce the Halting Problem to the Blank-tape Halting Problem [L-ToC-17]

例12.2 空白带停机问题 (blank-tape halting problem) 是另外一个可以通过停机问题简化来得到的问题。给定一个图灵机 M , 如果从空白带开始, 判定 M 会不会停机。这个问题是不可判定的。

为了表明这个简化是如何得到的, 假设我们给定 M 和 w , 首先利用 M 构造一个从空白带开始的新图灵机 M_w , 然后将 w 写到 M_w 上, 同时将 M_w 置于格局 $q_0 w$ 上。之后, M_w 和 M 就一致了。显然, M_w 在空白带上停机当且仅当 M 在 w 上停机。

假设现在空白带停机问题是可判定的。对于任意给定的 (M, w) , 我们首先构造 M_w , 然后对它应用空白带停机的算法。结论会告诉我们, 当 M 作用到 w 上时, M 是否会停机。由于对于所有的 M 和 w , 这个假设都成立, 所以空白带停机问题的算法就可以被转换成停机问题的算法。又由于后者是不可判定的, 所以空白带停机问题同样是不可判定的。 \square

A Common Approach in Establishing Undecidability Results [L-ToC-17]

♣ A common approach to establish undecidability results

- ◆ The construction in Example 12.2 is summarized in a block diagram in Figure 12.3.
- ◆ We first use an algorithm that transforms (M, w) into M_w ; such an algorithm clearly exists.
- ◆ Next, we use the algorithm A for solving the blank-tape halting problem, which we assume exists.
- ◆ Putting the two together yields an algorithm for the halting problem. But this is impossible, and we can conclude that A cannot exist.

♣ The common approach to establish undecidability results

- ◆ Replace the blank-tape halting problem into another problem.

Reducing an Undecidable Problem to Computing a Function

♣ A decision problem as a function

- ◆ A decision problem is effectively a function with a range $\{0,1\}$, that is, a true or false answer.

♣ Reducing an undecidable problem to computing a function

- ◆ We can reduce the halting problem (or any other problem known to be undecidable) to the problem of computing the function in question.
- ◆ Because of Turing's thesis, we expect that functions encountered in practical circumstances will be computable, so for examples of uncomputable functions we must look a little further.
- ◆ Most examples of uncomputable functions are associated with attempts to predict the behavior of Turing machines.

10/25/22 ***** Jingde Cheng / Saitama University *****

Reducing an Undecidable Problem to Computing a Function [L-ToC-17]

EXAMPLE 12.3

Let $\Gamma = \{0, 1, \square\}$. Consider the function $f(n)$ whose value is the maximum number of moves that can be made by any n -state Turing machine that halts when started with a blank tape. This function, as it turns out, is not computable.

Before we set out to demonstrate this, let us make sure that $f(n)$ is defined for all n . Notice that the set of all n -state Turing machines is finite. This is because Q and Γ are finite, so δ has a finite domain and range. This in turn implies that there are only a finite number of different δ 's and therefore a finite number of different n -state Turing machines.

Of course, not all n -state machines, there are some that always halt, for example machines that have only final states and therefore make no moves. Some of the n -state machines will not halt when started with a blank tape, but they do not enter the definition of f . Every machine that does halt will execute a certain number of moves; of these, we take the largest to give $f(n)$.

Undecidable Problems for Recursively Enumerable Languages [L-ToC-17]

THEOREM 12.3

Let G be an unrestricted grammar. Then the problem of determining whether or not

$$L(G) = \emptyset$$

is undecidable.

THEOREM 12.4

Let M be any Turing machine. Then the question of whether or not $L(M)$ is finite is undecidable.

10/25/22 ***** Jingde Cheng / Saitama University *****

The Post Correspondence Problem (PCP) [L-ToC-17]

The Post correspondence problem can be stated as follows. Given two sequences of n strings on some alphabet Σ , say

$$A = w_1, w_2, \dots, w_n$$

and

$$B = v_1, v_2, \dots, v_n,$$

we say that there exists a Post correspondence solution (PC-solution) for pair (A, B) if there is a nonempty sequence of integers i, j, \dots, k , such that

$$w_i w_j \cdots w_k = v_i v_j \cdots v_k.$$

The Post correspondence problem is to devise an algorithm that will tell us, for any (A, B) , whether or not there exists a PC solution.

THEOREM 12.7

The Post correspondence problem is undecidable.

Computable Functions [S-ToC-13]

❖ Computable functions

- ♦ A TM computes a function by starting with the input to the function on the tape and halting with the output of the function on the tape.

DEFINITION 5.17

A function $f: \Sigma^* \rightarrow \Sigma^*$ is a *computable function* if some Turing machine M , on every input w , halts with just $f(w)$ on its tape.

10/25/22

189

***** Jingde Cheng / Saitama University *****

❖ Computable function examples

- ♦ All usual, arithmetic operations on integers are computable functions.
- ♦ Computable functions may be transformations of machine descriptions.

The Post Correspondence Problem (PCP): An Example [L-ToC-17]

EXAMPLE 12.5

Let $\Sigma = \{0, 1\}$ and take A and B as

$$w_1 = 11, w_2 = 100, w_3 = 111,$$

$$v_1 = 111, v_2 = 001, v_3 = 11.$$

For this case, there exists a PC solution as Figure 12.7 shows.

w_1	w_2	w_3
1 1	0 0	1 1 1
v_1	v_2	v_3

FIGURE 12.7

If we take

$$w_1 = 00, w_2 = 001, w_3 = 1000,$$

$$v_1 = 0, v_2 = 11, v_3 = 011,$$

there cannot be any PC solution simply because any string composed of elements of A will be longer than the corresponding string from B .

Mapping (Many-One) Reducibility [S-ToC-13]

DEFINITION 5.20

Language A is *mapping reducible* to language B , written $A \leq_m B$, if there is a computable function $f: \Sigma^* \rightarrow \Sigma^*$, where for every w ,

$$w \in A \iff f(w) \in B.$$

The function f is called the *reduction* from A to B .

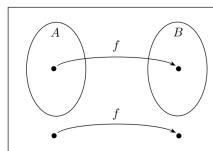

FIGURE 5.21

Function f reducing A to B

***** Jingde Cheng / Saitama University *****

Mapping (Many-One) Reducibility: Formal Definition [S-ToC-13]

❖ Converting questions

- ♦ A mapping reduction of A to B provides a way to convert questions about membership testing in A to membership testing in B .

- ♦ To test whether $w \in A$, we use the reduction f to map w to $f(w)$ and test whether $f(w) \in B$.

- ♦ The term *mapping reduction* comes from the function or mapping that provides the means of doing the reduction.

❖ Obtaining solutions

- ♦ If one problem is mapping reducible to a second, previously solved problem, we can thereby obtain a solution to the original problem.

Mapping (Many-One) Reducibility: Applications [S-ToC-13]

- ◆ The corollary 5.23 is a main tool for proving undecidability.

THEOREM 5.22

If $A \leq_m B$ and B is decidable, then A is decidable.

PROOF We let M be the decider for B and f be the reduction from A to B . We describe a decider N for A as follows.

$N =$ “On input w :

1. Compute $f(w)$.
2. Run M on input $f(w)$ and output whatever M outputs.”

Clearly, if $w \in A$, then $f(w) \in B$ because f is a reduction from A to B . Thus, M accepts $f(w)$ whenever $w \in A$. Therefore, N works as desired.

COROLLARY 5.23

If $A \leq_m B$ and B is undecidable, then A is undecidable.

Turing Reducibility

◆ Why Turing reducibility?

- ◆ Does mapping reducibility capture our intuitive concept of reducibility in the most general way? It does not.
- ◆ For example, consider the two languages A_{TM} and its complement A_{TM}^C .
- ◆ Intuitively, they are reducible to one another because a solution to either could be used to solve the other by simply reversing the answer.
- ◆ However, we know that A_{TM}^C is not mapping reducible to A_{TM} because A_{TM} is Turing-recognizable but A_{TM}^C is not.
- ◆ A very general form of reducibility, called **Turing reducibility**, captures our intuitive concept of reducibility more closely.

The Relationship of “Decidable Relative to” [S-ToC-13]

EXAMPLE 6.19

Consider an oracle for A_{TM} . An oracle Turing machine with an oracle for A_{TM} can decide more languages than an ordinary Turing machine can. Such a machine can (obviously) decide A_{TM} itself, by querying the oracle about the input. It can also decide E_{TM} , the emptiness testing problem for TMs with the following procedure called $T^{A_{\text{TM}}}$.

$T^{A_{\text{TM}}} =$ “On input $\langle M \rangle$, where M is a TM:

1. Construct the following TM N :
 $N =$ “On any input:
 1. Run M in parallel on all strings in Σ^* .
 2. If M accepts any of these strings, *accept*.”
2. Query the oracle to determine whether $\langle N, \emptyset \rangle \in A_{\text{TM}}$.
3. If the oracle answers NO, *accept*; if YES, *reject*.”

If M ’s language isn’t empty, N will accept every input and, in particular, input \emptyset . Hence the oracle will answer YES, and $T^{A_{\text{TM}}}$ will reject. Conversely, if M ’s language is empty, $T^{A_{\text{TM}}}$ will accept. Thus $T^{A_{\text{TM}}}$ decides E_{TM} . We say that E_{TM} is **decidable relative to** A_{TM} . That brings us to the definition of Turing reducibility.

Oracle Turing Machines [S-ToC-13]

◆ Oracle Turing machines

DEFINITION 6.18

An **oracle** for a language B is an external device that is capable of reporting whether any string w is a member of B . An **oracle Turing machine** is a modified Turing machine that has the additional capability of querying an oracle. We write M^B to describe an oracle Turing machine that has an oracle for language B .

◆ Note

- ◆ We are not concerned with the way the oracle determines its responses.
- ◆ We use the term oracle to connote a magical ability and consider oracles for languages that are not decidable by ordinary algorithms.

10/25/22

196

***** Jingde Cheng / Saitama University *****

Turing Reducibility: Definition [S-ToC-13]

◆ The definition of Turing reducibility

DEFINITION 6.20

Language A is **Turing reducible** to language B , written $A \leq_T B$, if A is decidable relative to B .

◆ The Turing reducibility and the mapping reducibility

- ◆ Turing reducibility is a generalization of mapping reducibility.

- ◆ If $A \leq_m B$, then $A \leq_T B$ because the mapping reduction may be used to give an oracle Turing machine that decides A relative to B .
